I Abstract

This diploma thesis describes how to create or convert traditional Java programs to desktop-like rich internet applications with the Google Web Toolkit.

The Google Web Toolkit is an open source development environment, which translates Java code to browser and device independent HTML and JavaScript.

Most of the GWT framework parts, including the Java to JavaScript compiler as well as important security issues of websites will be introduced.

The famous Agricola board game will be implemented in the Model-View-Presenter pattern to show that complex user interfaces can be created with the Google Web Toolkit.

The Google Web Toolkit framework will be compared with the JavaServer Faces one to find out which toolkit is the right one for the next web project.

Kurzfassung

Diese Diplomarbeit beschreibt die Erzeugung desktopähnlicher Anwendungen mit dem Google Web Toolkit und die Umwandlung klassischer Java-Programme in diese.

Das Google Web Toolkit ist eine Open-Source-Entwicklungsumgebung, die Java-Code in browserunabhängiges als auch in geräteübergreifendes HTML und JavaScript übersetzt.

Vorgestellt wird der Großteil des GWT Frameworks inklusive des Java zu JavaScript-Compilers sowie wichtige Sicherheitsaspekte von Internetseiten.

Um zu zeigen, dass auch komplizierte graphische Oberflächen mit dem Google Web Toolkit erzeugt werden können, wird das bekannte Brettspiel Agricola mittels Model-View-Presenter Designmuster implementiert.

Zur Ermittlung der richtigen Technologie für das nächste Webprojekt findet ein Vergleich zwischen dem Google Web Toolkit und JavaServer Faces statt.

III II Glossary

Adobe Flash is a runtime environment allowing web browsers streaming videos and drawing shapes. Many internet games and video players are built upon Flash.

Android “is an open-source software stack for mobile phones and other devices.” [Goo02a].

Application Programming Interface describes how software components should interact with each other.

BlackBerry is a mobile operating system developed by RIM (Research In Motion).

Cascading Style Sheets are used to describe the layout of a webpage.

Common Gateway Interface "The earliest Hypertext Transfer Protocol (HTTP) servers did not include any build-in mechanism for generating response dynamically. Instead, interfaces were provided for calling other programs to translate requests into run-time content. The first standard for dynamic web content was based on Common Gateway Interface (CGI), which specified a mechanism for web servers to pass request information to external programs, which were then run by the web server to generate responses at run-time.” [FK00, p. 3].

Conseil Européen pour la Recherche Nucléaire is a nuclear research center in Switzerland, Europe.

Cookie "A small piece of data sent by websites and stored in a user’s web browser to remember the website’s state or past user activity." [GHV].

Drag and Drop is the action of selecting one or more (virtual) objects and move them from one place to another with the mouse.

ECMAScript is the standardized client-side scripting language in the web. 'JavaScript, JScript and ActionScript are well-known dialects.' [Wik03].

Extensible Markup Language "XML was designed to transport and store data. HTML was designed to display data." [Reff] More information are available at [Wor11].

Flex Adobe "Flex is a powerful, open source application framework that allows you to easily build mobile applications for iOS, Android, and BlackBerry Tablet OS devices, as well as traditional applications for browser and desktop using the same programming model, tool, and codebase.” [Ado].

Graphics processing unit A graphic card has more, but less powerful, GPUs than a processor has CPUs, today. Many parallel algorithms like matrix multiplications are running faster using thousand GPUs instead of some CPUs.

GWT-Ext is a "Google Web Toolkit (GWT) wrapper around an earlier, 2.0.2 version of Ext JS. Being based on Ext JS, it has a very similar look and feel to" GXT. "Developing with GWT-Ext is more difficult [...], because the library is a wrapper around JavaScript and the Java debugger cannot help when there is a problem in the JavaScript code. Manual debugging is required. [...] Active development came to an end” in 2008. [Vau10, p. 9].
GXT is the short form of Ext-GWT, which stands for Extended GWT; we are using GXT instead of Ext-GWT to avoid confusion with GWT-Ext (it is also a GWT extension framework).

Hypertext Preprocessor is today's most common server-side scripting language.

iPad is Apple’s tablet computer; it is like an iPhone, but it has a bigger screen and you cannot call people.

iPhone is a smartphone with a touchscreen which is designed by Apple, it is running with Apple’s iOS mobile operating system.

Java development tools The Eclipse Java development tools "project provides the tool plug-ins that implement a Java IDE supporting the development of any Java application". [tea].

JavaServer Faces is Oracle’s replacement for JavaServer Pages (JSP), for more information see section 5.

JUnit "JUnit is a simple framework to write repeatable tests" in Java.

Microsoft’s Active Server Pages "ASP support multiple scripting languages, including PerlScript, JScript and VBScript. PerlScript is based on Perl and JScript based on JavaScript. But the default scripting language is VBScript, a subset of Microsoft’s popular Visual Basic programming language." [FK00, p. 6].

Model-View-Controller The model consists application data, view displays the model data to the user, controller receives the interaction events of the user and changes the model and view.

MySQL "MySQL is named after co-founder Monty Widenius’s daughter, My." [Orab] SQL stands for Structured Query Language.

Plain Old Java Object The given object is an ordinary (and not special) Java object.

RSA RSA, which is the abbreviation of the designers' names Ron Rivest, Adi Shamir and Leonard Adleman, is a public-key cryptography algorithm.

Scalable Vector Graphics "is a markup language for describing two-dimensional graphics applications and images". [Wor06].

Secure Sockets Layer are used to protect the traffic between server and web browser from a third party.

Server Side Includes The syntax is similar to Hypertext Preprocessor (PHP) (more information under http://www.apache.org/features/ssi).

Servlet 'Java Servlets are similar to CGI, you have a HTTP request as an input from the browser, and a Java program will produce a dynamic output.' [FK00, p. 7].

Smart GWT Smart GWT is a "framework that wraps the Smart Client JavaScript library in a similar way that GWT-Ext wraps Ext JS. Smart GWT has the advantage that it is still being actively developed." [Vau10, p. 9].

Standard Widget Toolkit is Eclipse’s graphical user interface for Java programming, a short comparison between Swing and Standard Widget Toolkit (SWT) can be found at [Son].
Struts The main idea of Apache Struts is to write web applications with the Model-View-Controller (MVC) pattern. It is mostly based on Servlets and JSP. [The08a].

Swing is the primary Java Application Programming Interface (API) for graphical user interfaces in desktop applications. It is part of the Java Runtime Environment.

Transport Layer Security The Transport Layer Security is the same like Secure Sockets Layer (SSL), but newer and more secure.

Uniform Resource Locator The syntax of Uniform Resource Locator is is:

```
scheme://domain:port/path?query_string#fragment_id
```

Vaadin Vaadin "is a server-side framework that uses a set of precompiled GWT components. [...] In Vaadin the browser client is just a dumb view of the server components and any user interaction is sent to the server for processing. [...] The main disadvantage of Vaadin is the dependency on the server. GWT or GXT’s JavaScript can run in a browser without needing to communicate with a server. This is not possible in Vaadin." [Vau10, p. 9].

W3C The World Wide Web Consortium develops the new web standards.

Web Workers "Allow scripts to run in the background to handle computationally intensive tasks, without blocking the UI or other scripts that handle user interactions." [GHV].

WebGL "makes it possible to display amazing realtime 3D graphics in your browser but what many people don’t know is that WebGL is actually a 2D API, not a 3D API." [Gre02].

WebOnSwing Swing based web development "framework that allows you to create web applications in the same way you develop a desktop one". [XOO09] You can use the MVC pattern and the Swingdesigner to develop your application.

Wicket "With proper mark-up/logic separation, a Plain Old Java Object (POJO) data model, and a refreshing lack of Extensible Markup Language (XML), Apache Wicket makes developing web-apps simple and enjoyable again." [The08b].
IV Credits

I would like to thank my parents Bettina and Bodo who supported me morally and financially during all nine semesters studying Applied Mathematics. Without them I would not have been able to finish it in such a short time with such a good result.

I owe special thanks to my supervisor Prof. Dr. Bernd Steinbach, who advised and supported me throughout the realization of this diploma thesis, and Dr. Peter Michel. Both of whom were the main reason for the topic of this work. I also want to thank them for the pleasant, more than three years long employment contract and for the trust and freedom they gave me to convert the research Java program into a web application with the framework of my choice.

Moreover, thanks go to my girlfriend Maren Lepke, who supported and helped me in the last months. She and Amanda Richardson improved this text in several proof-reading sessions.
1 Introduction

The research project "Trip-Matrix-Composite" of the TU Freiberg develops new high-performance steel composites. A user-friendly client program should save the research results of different institutes in a central database. The first software solution was implemented as Java Swing application. One drawback of desktop programs is that the user has to download and replace the application for each new feature or fixed bug. Web applications like Google Maps do not have this disadvantage, because the webserver always sends the newest version to the web browser. The main motivation to convert the existing Java application into a website was that some institute computers did not allow the installation of the Java Runtime Environment and so the database software could not run.

The Google Web Toolkit framework was the first choice as it has a Java to JavaScript compiler. This allows reusing Eclipse as integrated development environment and some of the program's Java code.

The aim of this diploma thesis is to answer the crucial question, whether it is possible to create a web application in an efficient way with the Google Web Toolkit, which has the same behavior as a normal Java desktop program.

In order to give a detailed answer to the above, the following issues must be discussed:

- Is it possible to extend the Google Web Toolkit (GWT) framework with JavaScript code in the same way a Java application can be extended with C or assembler code using the Java Native Interface? This is of great importance, because no framework is complete and other libraries have to be imported, which are often written in another language.
- Does GWT support techniques equivalent to Java reflection? This is necessary to control the runtime behavior for different operating systems or web browsers.
- Does GWT provide analog classes to the most important Java ones like ArrayList, HashMap, and so on? This would simplify the change from the Swing framework to the GWT one, because there is no need to learn many new classes.
- Two very important questions are: Are there Graphical User Interface (GUI) components in the GWT equivalent to Swing ones, and is the user event handling as powerful as in Swing? Answering these questions with yes, means that the web layout can be similar to the desktop one, and that both technologies have the same user experience.
- How can the GWT web application communicate with other Java and non-Java applications? And is it more difficult in GWT for the developer to exchange messages with others? This is significant so that distributed systems can be converted into a web application.
- Java applications can write the actual program state to disk. How does GWT save the web application state so that the user can restore it?
- Is GWT suitable for user interface design patterns? This is required when developing large scale applications containing several hundred thousand lines of source code.
- Java applications’ client-server communication can be secured with the iSaSiLk [sys] library. Is there a way to protect the communication between web applications and any server using the GWT framework?

Compared to JavaServer Faces 2.0, no standard for GWT exists and so the following question arises: Can the JavaServer Faces (JSF) framework create the same desktop-like web applications?

The following outline gives answers to the above questions:

Section 2 describes the basic web technologies. The historical development of the World Wide Web introduces different technologies. Then the five most important web standards will be
introduced: HyperText Markup Language (HTML), Cascading Style Sheets (CSS), JavaScript, HTML Document Object Model (HTML DOM) and Asynchronous JavaScript and XML (AJAX).

The third section is the biggest in this paper. It starts by showing existing web applications and games created with the Google Web Toolkit; most of them let the user believe that they are desktop applications running in the web browser. The rest of this section will take a very detailed look at the GWT toolbox while trying to answer most of the sub questions. This way an opinion can be formed as to how difficult it is for Java developers creating web applications with the GWT.

The next section explains how to structure large GWT applications. The famous Agricola board game is the example implementation for the Model-View-Presenter pattern. One advantage of this pattern is the opportunity to extend the desktop view with an optimized tablet one. Answers are given to the two issues, whether GWT is suitable for complex applications and whether the user can load saved game states into the web application.

The following section compares the Google Web Toolkit with JavaServer Faces. The comparison of the two web frameworks is done in five categories representing today’s major website kinds. This helps to figure out, if GWT is the right toolkit for different web projects.

Section six is about security in web applications. The aim is to check, if applications are as secure as normal Java desktop programs.

Afterwards, the result transferring the database desktop program into a rich internet application will be shown. This way a decision can be made whether it was possible to write a web application, which has the same behavior as the already existing database program.

The last section summarizes the result of the previous pages, and answers all introduced sub questions in a detailed way. A list with advantages and disadvantages of web applications helps to decide which desktop program types can be converted into web applications. This section finishes with future work.
2 Basics

2.1 Development of the World Wide Web

This section starts by explaining the history of the World Wide Web. A very nice illustration about the evolution of the web can be found at [GHV]. The timeline shows that many new technologies have been invented since 2009. At the end of this section it can be noticed that HTML 5, supported by all major web browsers since 2012, is an important milestone for web applications.

"Originally the Internet was created in 1969 by Advanced Research Projects Agency Network (ARPANET) to connect the Universities of the Air force. The main idea of ARPANET was to create a net with shared nodes. The resolution was to use a decentralized structure and so the network could survive a military attack. The Web itself is younger than the internet, the basics started at Conseil Européen pour la Recherche Nucléaire (CERN) about 1990. Tim Berners-Lee developed the first webserver and defined the first fundamentals of HTML. His hypertext definition means connecting documents with each other in a network-like structure. The first website is still available under [Tim12]. This site contains only text and hyperlinks (see figure A13); the source code (see listing A3) is interesting, too. ' [HWM06, pp. 32–33]

FileUpload (HTML 2.0), Cookies, Secure Sockets Layer (SSL) and CSS were introduced ca. five years later. This was the beginning of dynamic websites and languages like Hypertext Preprocessor (PHP) in 1995 or JavaServer Pages (JSP) in 1999. Rather nice definitions of static and dynamic web content can be found at [FK00, pp. 2–3].

A static website is requested from the web browser after the user has entered its address. The web server looks for the corresponding file and if it exists, the file content will be returned. Each document link in the HTML text will result in an extra file request by the web browser. "Documents that are requested never change regardless of who requested them, when they were requested, or which (if any) additional parameters are within the request. New versions of the documents might be placed on the server, but at any time, every request for those documents returns exactly the same results." [HWM06, pp. 32–33] The main characteristic of static web pages is that the server only detects the local files and uploads their contents unmodified.

But nearly all data is dynamic today. Examples are the current news pages or the own shopping card site at Amazon. "Dynamic web content, then, requires that the web server does some additional processing of the corresponding request in order to generate a customized response." [FK00, p. 3] Additional Uniform Resource Locator (URL) parameters are necessary to identify customized page requests. The timeline of [GHV] shows many new technologies about 1995. Some of them have been described above. From now on, not only static websites but also dynamic ones exist. This was the beginning of "Web 2.0" [Alb07].

Many new standards like Drag and Drop, Web Workers, WebGL, and File System Application Programming Interface (API) have been introduced since 2009. This is the turning point from traditional dynamic web pages to rich internet applications. For example Google Documents [Goob] is a web application having nearly the same behavior as Microsoft Office with Word, Excel and PowerPoint. The Aviary [Avia] web application, shown in figure A21, is a replacement for Microsoft Paint.

The beginning of the traditional dynamic web site was the birth of technologies and languages like Common Gateway Interface (CGI), Servlets, Server Side Includes (SSI), Microsoft’s Active Server Pages (ASP), PHP, JSP and many more. Eclipse’s Rich Ajax Platform (Eclipse RAP), GWT, Wicket, JSF, Flex, Struts, WebOnSwing (more can be found at [AW11, p. 43]) are now available to create rich internet applications.

Despite not needing to write any HTML and JavaScript code in GWT, it is useful to learn the basics of web languages and technologies. This allows to understand the GWT compiled output files and to extend the functionality of some widgets.
2.2 Hypertext Markup Language

The purpose of the Hypertext Markup Language is to structure documents and to create links between them. The layout and explicit view of a web page is done by the layout language Cascading Style Sheets and not by HTML. HTML can be written as plain text, and it does not have been compiled to a binary representation. This has the advantage that everyone can directly read the structure of a web page. Figure A14 shows the HTML code of the website tu-freiberg.de.

The most important parts of this markup language are the HTML tags describing the structure. There are two types of HTML elements: the paired and unpaired ones. The paired ones start with `<tag>` and end with `</tag>`. As the name already says the unpaired elements have no corresponding ending tag, their only content is `<tag>`. Each HTML element can have attributes describing extra information on it. The attributes are always listed in the start tag and they appear as name/value pairs. The general start tag structure is `<tag attributeName1=attributeValue1 ... attributeNameN=attributeValueN>`. The HTML tags and attribute names are case insensitive, but some of the values are case sensitive, e.g. the value of the title attribute. It is possible to nest tags between other open and end tags. This would look like the following `<tag1 attributeName11=attributeValue11 ... attributeName1N=attributeValue1N> <tag2 attributeName21=attributeValue21 ... attributeName2N=attributeValue2N> </tag2> </tag1>`. Please notice that the closing sequence of the end tags is the opposite order of the opening sequence of the start tags. Some parent attributes are inherited to their child elements; e.g. if `tag1` contains the attribute pair `color="blue"` and `tag2` does not contain the attribute name `color`, then it inherits it from `tag1`. In order to have a separation of concerns, neither styling tags like `<font>` nor styling attribute names like `color` should be used in the HTML code. The HTML style should always be declared in CSS. Table 1 shows the most important HTML tags.

Table 1: Most important HTML tags

<table>
<thead>
<tr>
<th>HTML tag</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>html</td>
<td>start tag represents the beginning of the HTML language and the end tag finishes the markup language</td>
<td><code>&lt;html lang=&quot;de&quot;&gt;...&lt;/html&gt;</code> means the entire content of the page is given in the German language.</td>
</tr>

2.3 Cascading Style Sheets

Cascading Style Sheets are used to describe the specific layout of websites. It can be used to customize the HTML code. There are four ways to define CSS styles:

1. tag level: HTML-tag[attribute condition]: { ... }
2. class level: .class-Name: { ... }
3. id level: #id-Value: { ... }

Figure 1: CSS example
2.4 JavaScript

‘ECMAScript is the standardized scripting language on the web. It is more commonly known as JavaScript.’ [Ecm03] Erik Meijer gives an appropriate definition of JavaScript: "JavaScript is an assembly language. The JavaScript + HTML generate is like a .NET assembly. The browser can execute it, but no human should really care what’s there." [Han]. In the same way a good C developer knows some background information about the lower-leveled machine language, a GWT developer can write better and more optimized code having knowledge about JavaScript. JavaScript is a dynamic, weakly typed, imperative, multi-paradigm and functional language. The syntax is C like. Different browsers implement different JavaScript dialects, e.g. Internet Explorer 9 implements Jscript 9, Google Chrome uses the V8 JavaScript Engine, and Mozilla Firefox uses the SpiderMonkey engine. One problem is that every JavaScript engine interprets the code differently. The conformity of the browser scripting engines to ECMAScript 5.1 can be tested at [Ecm03]. Internet Explorer 10 failed 8, Chrome 26 failed 15 and Firefox 20 failed 193 from 11573 tests (see figures A15, A16 and A17). Assuming that each of these browsers failed different tests, then the JavaScript engine difference between these three programs is 1.87%.

[Refe] is an introduction about JavaScript. Listing 2 and figure 2 show a simple calculator example written in JavaScript. The next subsection explains how to manipulate HTML elements in JavaScript to create dynamic user interfaces.

```
2 / 10 = 0.2
```

Figure 2: Simple JavaScript calculator example
Listing 2: Simple JavaScript calculator example

```html
<!DOCTYPE html>
<html>
<head>
	<title>My title</title>
</head>
<body>
	<a href="">My link</a>
	<h1>My header</h1>
</body>
</html>
```

Listing 3: Simple HTML code for Document Object Model (DOM) model

2.5 Hypertext Markup Language Document Object Model

The browser parses all HTML files and creates a Document Object Model before it displays the website’s content. The advantage of this intermediate step is that JavaScript can modify the
created DOM. This allows creating real dynamic web pages by adding, changing or removing elements of the Document Object Model. To get a better understanding of the HTML DOM structure, figure 3 shows the DOM model of the HTML code displayed in listing 3.

![HTML DOM diagram]

Figure 3: HTML DOM of listing 3. Copied from [Refd].

There are three ways to access the elements in the Direct Object Model:

- getting all elements with a given tag name, like `h1`
- getting all elements with a given class name
- getting the only element with a given id

**Node hierarchy**

'According to the official W3C standard, everything in an HTML document is a node:

- the complete HTML document is a document node
- every HTML element like `<div>` is an element node
- the text inside HTML elements are text nodes which can be accessed by the node’s `innerHTML` property
- every HTML attribute is an attribute node
- even comments are comment nodes in the DOM model

The nodes in the DOM tree are related to each other:

- the top node is called root element which is always the `<html>` tag
- every node except the root node has exactly one parent element
- a node can have no, one, or many children
- siblings (sisters or brothers) are nodes with the same parent node

In figure 3 `<html>` is the root node. It has the `<head>` node as first child and the `<body>` node as last child. The parent node of `<head>` is the `<html>` node. The child nodes `<head>` and `<body>` are siblings to each other.' [Refb]
Example manipulating the HTML DOM

Figure A18 and listing A4 show the complete source code and the corresponding screenshot of this example. The most important parts of the source code are explained below.

Line 21 defines an array containing the shape properties, which can be changed by the user later.

```javascript
21 var shapeArray = [['Rectangle', 'rect', ['x', 'y', 'width', 'height']], ['Circle', 'circle', ['cx', 'cy', 'r']], ['Ellipse', 'ellipse', ['cx', 'cy', 'rx', 'ry']], ['Line', 'line', ['x1', 'y1', 'x2', 'y2']], ['Text', 'text', ['x', 'y', 'htmlText']];
```

Listing 4: HTML code of DrawDomExample.html (line 21).

Lines 30 until 41 create dynamically the radio buttons by manipulating the browsers DOM hierarchy.

```javascript
30 var index;
31 for (index = 0; index < shapeArray.length; ++index) {
32 var radioInput = document.createElement('input');
33 radioInput.setAttribute('type', 'radio');
34 radioInput.setAttribute('name', 'shapes');
35 radioInput.setAttribute('onclick', 'showProps();');
36 radioInput.setAttribute('id', shapeArray[index][1]);
37 s.insertBefore(radioInput,b);
38 s.insertBefore(document.createTextNode(shapeArray[index][0]),b);
39 }
40 document.getElementById(shapeArray[0][1]).checked = true;
```

Listing 5: HTML code of DrawDomExample.html (lines 30-41).

A new HTML input element is created in line 32. The next lines 33 to 36 add some attributes to this element. The generated HTML code for index=0 is `<input type='radio' name='shapes' onclick='showProps();' id='rect'>`. The radio button will be added to the div element having the id "shapes" in line 37. At this point the radio button is visible in the web browser, because the created input node is available from the root node. The next two lines insert text and a line break into the div node. Before the loop is executed, the HTML code is `<div id="shapes">Shapes:<br><input type="button" id="add" value="add" onclick="add()"> <br></div>`. After two loop iterations with index=0 and index=1, the generated HTML code looks like `<div id="shapes">Shapes:<br><input type="radio" name="shapes" id="rect" onclick="showProps();"> Rectangle<br><input type="radio">Circle<br><input type="button" value="add" onclick="add()"> <br></div>`. The lines between 89 and 121 create a new Scalable Vector Graphics (SVG) shape, set the properties of the new shape and add it to the SVG draw container. The most important source code lines are:

```javascript
90 var svg = document.getElementById('svg');
95 shape = document.createElementNS('http://www.w3.org/2000/svg', shapeArray[index][1]);
109 shape.appendChild(document.createTextNode(n.value));
111 shape.setAttribute(n.id, n.value);
121 svg.appendChild(shape);
```

Listing 6: HTML code of DrawDomExample.html (lines 90, 95, 109, 111, 121).

Michael von Wenckstern: Web Applications Using the Google Web Toolkit
The function `changeProps` modifies the HTML DOM model by iterating over all attributes of the selected shape element and changing the attribute value to the new one in the input field. The `id` of the input field is the same as the name of the changed attribute name. The interesting code lines are:

```javascript
var a = shape.attributes;
for (var i = 0; i < a.length; ++i) {
  if (propAttr.indexOf(a[i].nodeName) !== -1) {
    a[i].nodeValue = document.getElementById(a[i].nodeName).value;
  }
}
```

Listing 7: HTML code of DrawDomExample.html. (lines 147-151)

### 2.6 Asynchronous JavaScript and XML

Asynchronous JavaScript and Extensible Markup Language (XML) are used to load server data in the background. This way the web browser will not block until the data is received. The advantage of AJAX in conjunction with HTML DOM is the ability to update a part of the website without reloading it completely again. Imagine the website is a large HTML page with many pictures and the latest news should be displayed in the left part of the web page. AJAX allows loading the news information in background; after the browser has received the data, the website's news part can be showed using HTML DOM. This way there is no need to reload the entire page, which may take several seconds to show up. Listing A5, figures A19 and A20 display the complete example. The AJAX code has been the same for all browser versions since 2007. The previous browsers Internet Explorer (IE) 5 and IE 6 had to create the AJAX object with

```javascript
xmlhttp=new ActiveXObject("Microsoft.XMLHTTP");
```

The timer will continue counting, when the website receives the latest news, at the bottom of the page. This proves that the page is not completely reloaded. Line 6 creates the AJAX request object. The next line assigns a function, which should be called after the request finishes, to the AJAX object. Line 12 sets the URL containing the actual data to the object. The last line of listing 9 starts the request by calling the `send` method. As earlier mentioned the data is shown to the user by manipulating the DOM model in line 9.
3 **GWT toolbox and compiler**

### 3.1 GWT in action

This section begins by showing web applications and games created with the Google Web Toolkit. [Goo11] displays the GWT showcase. The left frame contains several groups with the names of the basic GWT components. The behavior of the selected component can be tested in the right frame (see figure A22). The GWT user interface widgets have similar names and behaviors as the components used in Swing or Standard Widget Toolkit (SWT). However, the GWT library does not include advanced panel components with different layouts like GXT’s BorderLayoutContainer displayed in figure A24.

This is the reason why it is useful to extend the Google Web Toolkit with other libraries like GXT, GWT-Ext, Smart GWT or Vaadin. The unique characteristic of GXT is that it extends GWT using Java code. All the other above listed libraries only wrap their JavaScript classes into a Java one. The main disadvantage of wrapper classes is that they cannot be debugged in Eclipse, and this makes it more difficult to extend any widget of these libraries.

The GXT showcase is available at [Sen08b]. Many GXT widgets have a desktop-like layout and behavior. The advanced toolbar component shown in figure A23, is very similar to Microsoft’s ribbon bar. The GXT library also contains many layout panels such as Accordion-Layout, BorderLayout, CardLayout, HorizontalLayout, and VerticalLayout. This means GWT applications can use the same layout patterns as desktop ones.

Both showcases do not only display the components, they also show the source code of the selected example next to it. This makes both of them perfect learning places for new components. The GXT web desktop shown in figure A25, demonstrates the "power" of GXT. The web application can be tested at [Sen08a].

Figure A26 displays the GWT Quake 2 project, which can be found at [Ste]. The ego shooter online game uses WebGL to render the graphics, WebSocket to communicate with the other players, and WebStorage to save the actual games state. PlayN is a "GWT/Java based" [Plab] project "writing games that compile to" [Plac] five different platforms. The popular online game Angry Birds [Plaa] is created with the PlayN framework.

The mgwt [Dan06] toolkit creates websites which look and behave like native phone or tablet apps on iPhone, iPad, Android, or BlackBerry. Figure A27 shows a showcase [Dan] screenshot of mgwt. [api] demonstrates how to include Google Maps in GWT (see figure A28). Further information and the official site can be found at [Kei09] and [Bra].

The aim of this subsection was to give an overview of web applications. This may help to decide which framework should be used to convert a desktop program into a website. Another goal of demonstrating the different web pages is to motivate to learn a new API and how the GWT compiler works.

### 3.2 A short overview of the toolkit

GWT provides several tools moving desktop applications into the browser. Table 2 shows the most important parts of the toolbox.

### 3.3 GWT compiler and JSNI

#### 3.3.1 Overview of GWT compiler and JSNI

The first part of this section explains how the compiler works in general and where the compiler gets the corresponding JavaScript code from the Java one. This knowledge also allows extending the GWT toolkit with third-party JavaScript libraries.
Table 2: Overview of GWT toolbox

</tr>
</tbody>
</table>

This section assumes that both Eclipse and GWT are downloaded, installed and configured as shown in appendix A 1.

One way to understand the compiler basics is to compare some parts of the Java code with the generated JavaScript one in an example. After creating a new GWT Project¹ and a GWT module², Eclipse generates an example code as shown in listing 8. This code creates a web page containing only one button with the text "Click me!". After the button is clicked, a modal window with the message "Hello, GWT World!" pops up as shown in figure A29. The function onModuleLoad is equal to the standard Java function main, it is the starting point of the web application. Line 32 creates a normal button. It is added to the website in the line below. The rootPanel variable can be compared with the contentPane one of the main frame object in Swing. Line 34 sets the text of the button to "Click me" and in the next line a click handler is added, which shows the popup-window with the message "Hello, GWT World!" (line 37). After compiling this project³, the file ImageViewer.html and the folder de.tu_freiberg.informatik.vonwenckstern.ImageViewer can be found in the war directory. The

¹Files -> New -> Project ... -> WindowBuilder -> GWT Designer -> Model -> GWT Java Project; project name: DA_GWTCompile
²Module name: ImageViewer, Package name: de.tu_freiberg.informatik.vonwenckstern
³Google icon in toolbar -> GWT compile project ... -> Output style: Detailed
3 GWT TOOLBOX AND COMPILER

Listing 8: Excerpt from auto generated example source code by Eclipse; complete code (see listing A6)

```java
public void onModuleLoad() {
    RootPanel rootPanel = RootPanel.get();
    clickMeButton = new Button();
    rootPanel.add(clickMeButton);
    clickMeButton.setText("Click me!");
    clickMeButton.addClickHandler(new ClickHandler() {
        public void onClick(ClickEvent event) {
            Window.alert("Hello, GWT World!");
        }
    });
}
```

file ImageViewer.html contains all the static content for the web application and a reference to the dynamic content loader.

Opening this JavaScript file in a text editor shows that the web content is loaded dynamically, depending on which browser version is used (see listings A6 and A8). This is necessary because every browser has a different layout and JavaScript engine. This is one big advantage of the GWT framework, because the Java code only has to be written once and the compiler will handle the browser-specific code.

Generally GWT compiles by substituting the Java code with the given JavaScript one using JavaScript Native Interface (JSNI). Listing 9 displays the JSNI implementation of `window.alert`, which can be opened by pressing the control key and clicking with the mouse on the alert function invocation in Eclipse.

```
public static native void alert(String msg) {
$wnd.alert(msg);
}
```

Listing 9: JSNI implementation of `window.alert`

This means the line `Window.alert("Hello, GWT World!")` will be translated to `$wnd.alert('Hello, GWT World!')` which can be found e.g. in Opera’s specific website at line 341.

The next paragraphs give more details about JavaScript Native Interface. JSNI is the bridge between Java and JavaScript. Because only the web browser is able to execute JavaScript code, JSNI cannot be used on the server-side part. This passage shows how to pass Java objects to JavaScript, load external JavaScript libraries, wrap JavaScript code as Java classes, and execute Java code from JavaScript. This section intends to give an understanding of the lowest structure of GWT components. It also explains how different libraries like the Smart GWT one work. Another aim of this subsection is to describe JSNI in such a way that Google’s implementations of different functions are readable. This removes the mystery factor from the compilation process.

6de.tu_freiberg.informatik.vonwenckstern.ImageViewer
6de.tu_freiberg.informatik.vonwenckstern.ImageViewer.nocache.js
7This means if Firefox (user.agent = gecko1_8) is requesting ImageViewer.html then the dynamic content loader will return D86C78425EBF3471F02A10176A0C7644.cache.html and if this web page has been viewed with Internet Explorer 9 (user.agent = ie9) the site D2314070AA3C3D47EA100703B721615D.cache.html will be loaded.
8e.g. Firefox uses SpiderMonkey [Moz08] and IE9 uses Chakra [Mica]
9JavaScript uses single quotation for strings instead of double ones
1067FDEAF3397887CF1E2008A6BC06B53D.cache.html

Michael von Wenckstern: Web Applications Using the Google Web Toolkit
It is not recommendable at all to write much JavaScript code, because it is like assembly. This means the JSNI code will not run on all browsers or it will be interpreted differently from browser to browser. The JavaScript code cannot be debugged in Eclipse, it can introduce memory leaks, and due to its weak typed nature, GWT cannot perform any syntax check on JSNI. Another drawback of JSNI code is that the compiler is not able to optimize it as well as Java code, e.g. by changing global variable names to shorter ones, which will shorten the output code and speed up the entire application. Some books advise using (plain) JSNI to implement new browser functions in GWT; but if JavaScript Overlay Types are available, then these should be favored over (plain) JSNI. Overlay Types will not be covered in this paper. GWT 2.5 uses this technique to implement new HTML5 features.

JSNI uses the Java Native Interface ("JNI enables the integration of code written in the Java programming language with code written in other languages" [Ora03]) to implement JavaScript code. For this reason the function declaration contains the additional keyword native, and "the body of a native method is given as a semicolon only, indicating that the implementation is omitted, instead of a block" [Gos07, p. 224]. This is why the JavaScript code is inside a Java comment block. /*{- and }-*/ are the start and end points of the JavaScript method, so the compiler will notice it as JavaScript code instead of a usual comment. If the return type of the native method is not void, then the JavaScript code has to return an object of the correct type. Returning a newly created Java object in the JavaScript code as well as a long number is not allowed. Table 3 shows all possible return types.

Table 3: Passing JavaScript values into Java code (copied from [Goo06b])

<table>
<thead>
<tr>
<th>Outgoing Java type</th>
<th>What must be passed</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>JavaScript string, as in return ‘boo’;</td>
</tr>
<tr>
<td>boolean</td>
<td>JavaScript boolean value, as in return false;</td>
</tr>
<tr>
<td>long</td>
<td>disallowed</td>
</tr>
<tr>
<td>Java numeric primitive</td>
<td>JavaScript numeric value, as in return 19;</td>
</tr>
<tr>
<td>JavaScriptObject</td>
<td>native JavaScript object, as in return document.createElement(‘div’)</td>
</tr>
<tr>
<td>any other Java Object (including arrays)</td>
<td>Java Object of the correct type that must have originated in Java code; Java objects cannot be constructed from &quot;thin air&quot; in JavaScript</td>
</tr>
</tbody>
</table>

Java to JavaScript, will be explained. Table 4 lists all possibilities of transferring Java values to JavaScript. Since JavaScript does not expect any types, typing incompatibility can occur. Problems which can be caused by a weakly-typed language are shown in listing 10 and figure A30.

```java
3 function addWithOut(a, b) {
4 var c = a + b;
5 alert(‘Result without type conversion is: ‘ + c);
6 }
7 function addWith(a, b) {
8 var c = Number(a) + Number(b);
9 alert(‘Result with type conversion is: ‘ + c);
10 }
```

Listing 10: Excerpt from code showing typing conversion in JavaScript; complete code (see listing A9)

---

9 further information at [Goo06c]
10 see [Goo06c] and [Goo06f]
Table 4: Passing Java values into JavaScript (copied from [Goo06b])

<table>
<thead>
<tr>
<th>Incoming Java type</th>
<th>How it appears to JavaScript code</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>JavaScript string, as in var s = 'my string';</td>
</tr>
<tr>
<td>boolean</td>
<td>JavaScript boolean value, as in var b = true;</td>
</tr>
<tr>
<td>long</td>
<td>disallowed</td>
</tr>
<tr>
<td>other numeric primitives</td>
<td>JavaScript numeric value, as in var x = 42;</td>
</tr>
<tr>
<td>JavaScriptObject</td>
<td>JavaScriptObject that must have originated from JavaScript code, typically as the return value of some other JSNI method.</td>
</tr>
<tr>
<td>Java array</td>
<td>opaque value that can only be passed back into Java code</td>
</tr>
<tr>
<td>any other Java Object</td>
<td>opaque value accessible through special syntax</td>
</tr>
</tbody>
</table>

This is why it is important to be careful in the JavaScript world. Whenever parameters need to have a special type, the type conversion must be done manually as explained in [Gar05].

Java variables inside JSNI functions can be accessed by the following pattern: `object-Name.@fully_qualified_class_name::name_of_variable` and `@fully_qualified_class_name::name_of_variable` for static fields.

Calling java functions from JavaScript works with almost the same pattern: `objectName.@fully_qualified_class_name::method_name(parameter_signature)(arguments)`. Table 5 shows the most common parameter signatures. Listing A10 and figure A31 display a complex example with many comments on how the interaction between Java and JavaScript works. It is also possible to send and receive information from the server by using JSNI, more information is available at [HT07, pp. 323-331].

After becoming familiar with the basics of JSNI, the next passage explains how to load and wrap a JavaScript library so that it can be used in GWT without any JavaScript code later. All necessary steps are shown by a simple example. The highlighter JavaScript library will be used to emphasize keywords of different programming languages. Firstly, the library has to be downloaded from [Ale05] and unzipped. Secondly, the `syntaxhighlighter_3.0.83` folder will be copied into the Eclipse’s web directory. Thirdly, the library must be loaded by either including the lines showed in listing 11 in the `ImageViewer.html` document or by adding the code from listing 12 in the application’s module file. Wrapping the constructor of the JavaScript

---

11 maybe a newer version have been downloaded and so the folder name is slightly different
12 mostly named war or WebContent
library object into Java functions will be done in three steps: writing the implementation class, creating the JavaScriptObject class and packing the JavaScriptObject class in a Java GWT widget. The implementation class will contain all the JSNI code for interacting with the JavaScript library. The example JavaScript code explains how to use this library; unfortunately the example contains only HTML code (see listing 13) and no JavaScript one.

This means the HTML code must be ‘converted’ into JavaScript as listing 14 illustrates.

---

Michael von Wenckstern: Web Applications Using the Google Web Toolkit
Line 3 creates the pre object and two lines later it is added to a given div element. Lines 6 and 7 set the properties of this object: the code and the language (in this example it is JavaScript) which should be highlighted. Listing 15 shows the code of the implementation class.

```
5 public class SyntaxHighlighterImpl {
6     public native SyntaxHighlighter create(Element el) /*-*/
7         { synHighPre = document.createElement('pre');
8             el.appendChild(synHighPre);
9             return synHighPre;
10         }/*-*/;
11
12         public native void setLanguage(SyntaxHighlighter sh, String language) /*-*/
13             { sh.className = 'brush:' + language + ';';
14             }/*-*/;
15
16         public native void setCode(SyntaxHighlighter sh, String code) /*
17             { sh.innerHTML = code;
18             }/*-*/;
19     }
```

Listing 15: SyntaxHighlighterImpl.java in LoadJavaScript library’s project (implementation class)

Line 6 defines the Java create method, line 7 creates the JavaScript object and line 9 returns it. Lines 13 and 17 set the properties of the JavaScript object which was passed as an argument of the functions setLanguage and setCode. Now the JavaScript Object class SyntaxHighlighter, which is similar to a JavaScript handle for passing around in Java code, will be created. The handle is an opaque object in the Java world, because it is neither possible to see its properties nor is any Java code able to call its methods. The handle’s properties and execution of its methods is only available in JavaScript code. Listing A13 demonstrates the code of the JavaScript Object class. This class just contains normal Java functions which invoke the corresponding JSNI methods of SyntaxHighlighterImpl. Finally, the widget class having DOM elements as placeholders will be created. These placeholders will be passed as arguments to the create function of the implementation class. The DOM elements in the widget class can be compared to the empty div-tag in listing 13 at line 1. Since this case is so simple and only one placeholder is needed, the widget extends the HTML component and passes its own element as a placeholder to the implementation class (see line 18 at listing A14). This widget also contains the other two functions to change the JavaScript object properties. After having wrapped the SyntaxHighlighter JavaScript library into GWT, the widget can be used as a normal Java object. Listing A15 shows how to use the wrapped SyntaxHighlighterWidget, figure A32 displays the result. Whenever the SyntaxHighlighterWidget is being used, it is not obvious that a JavaScript library is doing all the work. This is an advantage of GWT, because the developer can stay in its Java world by using JavaScript libraries after they have been wrapped successfully.

The Smart GWT library works in the same way; it is a wrapper for the SmartClient JavaScript framework. This is the reason why it is very difficult to modify widgets of the Smart GWT library, because the code has to be written in JavaScript. In general the GWT compiler substitutes Java code by JavaScript one or replaces Java function calls by direct JavaScript method invocations to a library, and all this by using the JSNI interface. However, there are still some questions which have still not been answered:

- How does the compiler generate several browser outputs? (Until now, no browser-specific JavaScript or Java code has been defined.)

Michael von Wenckstern: Web Applications Using the Google Web Toolkit
3 GWT TOOLBOX AND COMPILER

- Why do the output files have such strange names and what is meant by .cache.html and .nochache.js?
- What optimizations does the GWT compiler carry out (Java and/or JavaScript code)?

These questions will all be answered in the next subsections.

3.3.2 Deferred binding and bootstrapping process

Deferred Binding, which is the analogue to Java reflection, “is a technique used by the GWT compiler to create and select a specific implementation of a class based on a set of parameters.”

By default GWT generates a specific JavaScript version for each browser. Other parameters can be for example the language and device type. If the project supports desktop, tablet and mobile versions in the languages English, German, French, Russian, Italian, Chinese and Spanish, then the compiler will generate $6 \cdot 3 \cdot 7 = 126$ specific website versions (see figure 4). The compiler generates a huge number of files in order to reduce the download size and increase the execution speed. Because if it created just one file, the mobile phone user would have to download all the JavaScript code for every browser, the code for all the languages as well as the widgets and images in three possible sizes: small for mobile, medium for tablet and large for the desktop version. This would be in spite of only one browser and language being used and there not being use of the medium and large version on a mobile phone. It is very unlikely that a customer visiting a sale website with a mobile phone will come back when the site forces the browser to download all 126 specific versions. This download process would slow down the loading process and it would take several minutes to build the website.

Another drawback of delivering just one file to all web browsers is that this file contains many conditions which allow the JavaScript engines to execute the specific code depending on the parameter set. Listing 16 gives an example code, which must be executed every time a new item is shown. In this example eight instructions are needed, because the program executes seven condition tests for all languages and one assignment. If the server delivers the language-specific code, then only the one assignment instruction description = 'Intensivere Farben. Schärfere Kontraste. Geringere Blickwinkelabhängigkeit.' will be executed. Hopefully this extremely theoretical example has shown the advantage of deferred binding.

Figure 4: Files the compiler generated

![Diagram showing the compiler generated files with combinations of languages, devices, and browsers.](image)
The drawback of this technique is the long compilation time to create the 126 HTML files. This section part will start with deferred binding by replacement. "Replacement means overriding the implementation of one java class with another that is determined at compile time." [Goo06a] This mechanism will be described in an example which creates a special message depending which browser is used (see figure A33). At first the general interface class (see listing 17) will be created.

```
public interface Status {
    public void getStatus();
    public Widget asWidget();
}
```

Listing 17: Status.java in deferred binding with replacement project (package name and imports are omitted)

The following classes StatusLabel (see listing A17), StatusLabelIE9 (see listing 18) and StatusLabelFF (see listing 19) will implement this interface.

```
public class StatusLabelIE9 extends Label implements Status {
    @Override
    public void getStatus() {
        this.setText("You are using Internet Explorer 9.");
    }
}
```

Listing 18: StatusLabelIE9.java in deferred binding with replacement project (package name and imports are omitted)

```
public class StatusLabelFF extends Label implements Status {
    @Override
    public void getStatus() {
        this.setText("You are using Firefox.");
    }
}
```

Listing 19: StatusLabelFF.java in deferred binding with replacement project (package name and imports are omitted)

The code `Status status = GWT.create(Status.class)` creates the Status object in the ImageViewer (complete code see listing A16) class. In order to use the compiler’s deferred binding mechanism, the new keyword, as shown in the following code line `Status status = new

Michael von Wenckstern: Web Applications Using the Google Web Toolkit
Status(), cannot be used to create any specific code. The binding rules are defined in ImageViewer.gwt.xml (see listing 20).

Listing 20: ImageViewer.gwt.xml in deferred binding with replacement project (module definition is omitted)

Lines 7 to 9 describe the default case with the standard replacement. Lines 12 to 18 say that the interface should be replaced with the Mozilla specific implementation if the user agent is either gecko or gecko1_8. The next block declares that the Status interface should be replaced by Internet Explorer 9 specific implementation if the user agent is ie9.

The passage explains deferred binding using generators. "Generators are classes that are invoked by the GWT compiler to generate a Java implementation of a class during compilation." [Goo06a] Instead of writing a different class for each browser as in the replacement example above, a generator class - which automatically writes the source code classes for the different browsers - will be created at compile time. The advantage of this technique is that there is no need to copy one file several times and just change a little part of it. The disadvantage is that it is more complex and strange errors can occur during the compilation process.

The best way to understand this method is to show an example. For reason of comparability, the same example as above is used. This is why the files ImageViewer.java (see listing A16), Status.java (see listing 17) and StatusLabel.java (see listing A17) are the same. The module’s project file is shown in listing 21. Lines 5 to 7 say that the compiler should generate the browser-specific Java file for the Java type Status. Instead of implementing the classes StatusLabelFF (see listing 18) and StatusLabelIE9 (see listing 19), the Generator class - which creates these classes - will be defined. The StatusGenerator class is displayed in listing 22. It is important that the generator class is not in the client package, because this code cannot be translated to JavaScript.
Listing 21: ImageViewer.gwt.xml in deferred binding with generator project (module definition is omitted)

```java
15 public class StatusGenerator extends Generator {
22 public String generate(TreeLogger logger, GeneratorContext context,
23 String typeName) throws UnableToCompleteException {
24     userAgent = context.getPropertyOracle().
25         getSelectionProperty(logger, "user.agent").
26         getCurrentValue();
27     SourceWriter sw = getSourceWriter(typeName, context,
28         logger, userAgent);
29     sw.println("@Override");
30     sw.println("public void getStatus()");
31     sw.println("this.setText("You are using "+ browser + "");
32     sw.println(");
33     sw.commit(logger);
34     System.out.println("class + typeName + userAgent + 
35                         Generated was created successfully");
37     return typeName + userAgent + " Generated";
46     public SourceWriter getSourceWriter(String typeName,
47         GeneratorContext context,
48         TreeLogger logger, String userAgent) throws 
49     NotFoundException {
50         String simpleName = classType.getSimpleName();
51         simpleName = simpleName + userAgent + " Generated";
52         composer.setSuperclass("com.google.gwt.user.client.ui.
53                         Label");
55         composer.addImplementedInterface("de.tu_freiberg.
56                         informatik.vonwenckstern.client.Status");
57         composer.addImport("com.google.gwt.user.client.ui.Label");
58         SourceWriter sw=composer.createSourceWriter(context,
59             printWriter);
64     return sw;
73 }
74 }
```

Listing 22: StatusGenerator.java in deferred binding with generator project (complete code see listing A18)

In line 15 the class StatusGenerator extends the standard Generator class which generates the source code during the deferred binding process. Because the standard Generator class is abstract, the generate method must be implemented. In line 22 it creates the specific class and returns the name of the new class, which the compiler uses instead of the requested one. The TreeLogger class is an abstract class, which logs several messages during deferred binding. The GeneratorContext interface provides several metadata for deferred binding. The metadata are:
• The parameter set, which is used to generate the class.
• The typeName is the name of the requested type, which will be substituted. In this case is
typeName = 'Status', because the following expression Status status = GWT.create
(Status.class) in the ImageViewer.java file invoked the deferred binding generator.

Line 27 returns the user agent for which the compiler generates the specific file. Line 33 calls
the function getSourceWriter, which creates an empty class, e.g. Statusgecko1_8Generated,
in line 82. The method also includes all required imports in line 90. The created class extends
the Label class (see line 86) and implements the Status interface (see line 88). Line 100 returns
the SourceWriter object. The result is used to add the function implementation of the generated
class in lines 38 to 41. The command sw.commit(logger) flushes all the generated codes into
a Java file in line 45, and the logger notes that the file is completely created. Line 47 returns
the generated file name. Compiling this project creates the output as shown in listing 23. The
console text displays all six browser-specific generated Java files, which will be used in the
compilation process to generate JavaScript code later.

Listing 23: Compiler output in deferred binding with generator project (complete code see
listing A19)

Figure A34 shows the compiled result in different web browsers. In the second subfigure Internet
Explorer 9 was running in compatibility mode. It displays the message 'Internet Explorer6'
instead of its real compatibility user agent 'Internet Explorer7', because the GWT 2.4 compiler
creates only specific web pages for the user agents ie6, ie8, ie9 and more, but no website for ie7.
This is why the bootstrapping process loads the specific code for ie6.

The next paragraph explains the bootstrapping process in more detail, and tries to explain
the meaning of generated filenames.

Listing 24: HTML example describing the order of loading a web page (copied from
[Goo06h])

Michael von Wenckstern: Web Applications Using the Google Web Toolkit
Listing 24 shows a bootstrapping sequence example. Figure 5 illustrates the loading sequence of listing 24. Firstly the entire HTML file will be downloaded and parsed. If it contains links to other documents like images or scripts then these files will be transferred in order of their appearance. There are two rules: Image files will not block the downloading process, but script files will block downloading and the process will only continue if the script document has completed transferring.

<table>
<thead>
<tr>
<th>conection 1</th>
<th>HTML</th>
<th>bigImage0.jpg</th>
<th>blocked</th>
<th>bigImage1.jpg</th>
<th>myApp.nocache.js</th>
<th>&lt;hashname&gt;.cache.html</th>
<th>external-Script1.js</th>
<th>onModuleLoad() called</th>
<th>wait</th>
</tr>
</thead>
</table>

| conection 2 | external-Script0.js | really bigImage2.jpg | body.onLoad() called |

Figure 5: Loading sequence of a website (summary from [Goo06h])

The <hashname>.cache.html files contain the actual JavaScript program code written in an HTML file. The JavaScript code is wrapped, because some browsers do not support compression of pure JavaScript. "Since the GWT mantra is no-compromise, high-performance AJAX code" [Goo06d] the compiler wraps the program code in an HTML file to avoid sending the application code uncompressed. The <hashname> is the md5 sum of their content. This guarantees the web browser that this content will never change and so the file can and should be cached, which is the reason for their .cache.html extension. Modifying the Java code of any project will change the corresponding JavaScript and the <hashname> will be different. This means that the browser has to download a different file and will not use the cached one. The myApp.nocache.js contains the code to find the browser-specific program version and all other required parameters. After the parameter set has been figured out, the browser starts loading the associated <hashname>.cache.html file. This is the place where deferred binding occurs at runtime. As the filename indicates, this JavaScript file should never be cached as the GWT compiler generates different contents under the same filename every time. This means if the browser cached this file, then it would use the old cached content instead of downloading the new one. The <hashname>.gwt.rpc file contains all types which implement java.io.Serializable interface and are allowed to be serialized from client to server or vice versa due to security reasons. The <hashname>.cache.png files contain several images which are bundled together to one big image. As above, the hashname is the md5 hash of its content, so this name is unique and can be cached by the browser. The advantage of image bundles will be discussed in section 3.8.1. The last compiler generated file is the hosted.html one, which contains the HTML and JavaScript code for the hosted mode. This code is looking for and connecting to the GWT plugin, which interprets Java code as JavaScript, and displays errors from the GWT plugin in the web browser. Since the GWT compiler does a lot of optimizations like creating cached and no-cached files, compiled AJAX applications are much faster than handwritten ones.

3.3.3 GWT compiler steps and optimizations

The aim of this subsection part is to describe the compiler steps and its optimizations, which keep the application relatively small although many libraries were imported. This allows downloading and starting the web application in a short period of time.

Since the GWT compiler is a normal Java program, the compilation process can be debugged in Eclipse to understand the compilation steps in more detail. This paragraph describes the

14for "real" programs containing several forms and controls and not just only one button, where the bootstrapping overhead is larger than the application code itself
setup to start debugging the compilation process. Firstly a normal GWT project with the name "DA_GWTCompiler_Optimizations" will be created, secondly the Eclipse debug configuration will be opened, a double click on Java Application will be done and "Compiler" will be entered as debug configuration name. In the Main tab the Project field is set to "DA_GWTCompiler_Optimizations", the Main class to "com.google.gwt.dev.Compiler" and check the option "Stop in main". The following text "-logLevel ALL -style PRETTY de.tu_freiberg.informatik.vonwenckstern.ImageViewer" will be entered into the Program arguments field of the Arguments tab. In the same tab the working directory has to be "default". User Entries have to be selected in the Classpath tab. After the Advanced ... button on the right side has been toggled and Add External Folder selected in the popup dialog, the ".../DA_GWTCompiler_Optimizations/src" folder can be chosen in the tree. After pressing the Debug button, the Eclipse debugger will stop at the main function. This is the starting point to explore the compilation process.

Abstract Syntax Tree and Visitor Pattern

Before discovering the GWT compiler, it is better to mention Abstract Syntax Tree (AST). The best way to understand AST is by playing around with the Eclipse AST plugin (download site at [Tea]), which shows the AST tree of a selected Java file. AST is a "precise and fully resolved compiler parse tree" [Aes] representing the syntax of a Java source file. Some Eclipse AST node types are:

- MethodDeclaration for a function,
- JavaDoc for the /** ... */ comments over the method declarations,
- Modifiers are keywords like public, static, native and so on.

All Eclipse AST node types are listed in table A3. For a better understanding of the Abstract Source Tree, figure A35 shows the AST of the simple Java class shown in listing A20. During the compilation process the AST will be changed several times, e.g. after deleting unused variables and methods. Implementing the compiler can be done using different patterns like the inheritance pattern, visitor pattern or the compiler matrix pattern. Since the inheritance pattern is the naive way of implementing the compiler and Google uses the visitor pattern for their compilation process, the matrix pattern (for more information see paper [XW]) will not be described in this subsection. Using the inheritance pattern means (1) declaring an abstract interface for all AST nodes containing virtual methods as node operations (like code error checking, optimizations, code generation and obfuscation) and (2) defining a class for each AST node, which implements the methods inherited from the super node class. Figure A39 shows an Unified Modeling Language (UML) diagram using this pattern. The disadvantage of this pattern is that each node class implements many methods with different algorithms. As a result algorithms such as error checking are spread across numerous nodes, having to introduce global variables or pass many arguments by reference for each method call. It is also nearly impossible to change or add any algorithm later because all the functions have to be updated in different node classes by considering the calling hierarchy order. A better solution would be the separation of the algorithm from the object structure. The double dispatch pattern solves the separation by encapsulating all methods performing one operation into a single class.

This way all required variables for executing this algorithm are in one class and so there is no longer need for global variables or passing references. Another advantage is that the classes defining the AST structure were not modified, and so new operations -by creating new classes- can be added. This is especially important when there are no writing rights in the operation classes, e.g. in shipped JAR archives. Figure A40 displays the UML diagram, which manipulates Java AST using the inheritance pattern and the double dispatch one. Since the
double dispatch pattern is not natively supported in Java\textsuperscript{15} it must be emulated by an extensive usage of the instanceof operator (see shape example at listing A21) or by the visitor pattern. To implement the visitor pattern a Visitor interface or a superclass must be created. This would contain different visit methods, and a Visitable interface or an extra class containing an accept method which receives the Visitor as argument.

It is important that each class inheriting the accept method needs to override this one, even if these are always the same lines of code return visitor.visit(this), because this is the point where double dispatching occurs. More precisely: Firstly the accept method of element A is invoked with parameter B, e.g. A.accept(B). The specific method invocation is chosen by the dynamic type of the element A (single dispatch) and the static type of the Visitor B. Secondly when the visitor calls the associated visit(this) method, its implementation is chosen by the dynamic type of the Visitor B and the static type of the element A known from the implementation of accept(this), which is the same as the dynamic type of the element. This means the double dispatch mechanism is emulated by executing single dispatching twice in succession.

Listing A22 implements the shape example using the visitor pattern. In the example code there are two shapes \texttt{shape1 = new Triangle()} and \texttt{shape2 = new Heptagon()}, which have the same static type \texttt{ShapeVisitor}. The line \texttt{shape1.accept(shape2)} is the starting point of the double dispatch pattern. Firstly Java does the single dispatch, this means \texttt{Triangle::accept(ShapeVisitor \texttt{shape2})} is called, because \texttt{shape1} has the dynamic type \texttt{Triangle} and \texttt{shape2} has the static type \texttt{ShapeVisitor}. As mentioned above, every accept function calls only \texttt{visitor.visit(this)}. The this variable has the static type \texttt{Triangle} now, because the \texttt{Triangle::accept(ShapeVisitor \texttt{visitor})} method has been invoked and the \texttt{Triangle} class overrides the accept method to change the static type of the this variable to its own class type \texttt{Triangle}. The line \texttt{visitor.visit(this)} in the \texttt{Triangle::accept(ShapeVisitor \texttt{visitor})} method, where \texttt{visitor} is equal \texttt{shape2}, invokes the function \texttt{Heptagon::visit(Triangle)}, because the dynamic type of \texttt{visitor} is the dynamic type of \texttt{shape2}, being \texttt{Heptagon}, and the static type of this is \texttt{Triangle}. This means after the visitor pattern has been executed, the code \texttt{shape1.accept(shape2)} invokes the function \texttt{Heptagon::visit(Triangle)}, which represents the double dispatch function call of the dynamic types of the two shape objects.

The visitor pattern also has disadvantages, for example after adding a new node type, all visitor classes have to be changed. For Google this is not really a disadvantage, because the AST node types represent the Java language specification and this will not recently change. On the other hand the advantage of using the visitor pattern is great, because it is easy adding new compiler steps or changing existing ones.

This paragraph finishes by showing how to use the Eclipse AST library together with the visitor pattern. The example shown below modifies an existing Java source code. The example can be seen as a little prototype showing how a compiler may work. Figure A41 displays the UML diagram. Listing 25 gives a sample implementation of the accept method for the classes extending ASTNode. Source code for all classes, which extend ASTNode, is available at [Ecl07]. The traversing process starts every time by calling CompilationUnit::accept(ASTVisitor). The next lines describe the process for the FieldPrinter. This means firstly FieldPrinter::visit (CompilationUnit) is called which is not implemented in the FieldPrinter class. This means ASTVisitor::visit(CompilationUnit) is invoked, which will do nothing else than returning true, and so in the accept method all the children nodes of CompilationUnit node\textsuperscript{16} will accept the FieldPrinter as visitor. This means once FieldPrinter::visit(PackageDeclaration), many

\[15\]Java supports only the single dispatch mechanism, which invokes the method at runtime depending at the object's type which is calling the function. Java ignores the runtime types of the arguments of a method by invoking it. Method overloading will be done by matching the argument types for function calls at compile time and not at runtime.

\[16\]having the types PackageDeclaration, ImportDeclaration and TypeDeclaration (see figure A35 for ASTNode hierarchy)
```java
void accept(ASTVisitor visitor) {
    boolean visitChildren = visitor.visit(this);
    if (visitChildren) {
        // visit children in normal left to right reading order
        for (ASTNode child : children) {
            child.accept(visitor);
        }
    }
}
```

Listing 25: Prototype implementation of the accept method for the classes extending ASTNode

Times FieldPrinter::visit(ImportDeclaration) and several times FieldPrinter::visit(TypeDeclaration) are called. If FieldPrinter::visit(P) returns true, then FieldPrinter::visit(S) will be called for all children nodes S of the parent node P, otherwise the entire sub tree of the parent node P will be skipped and will not be visited. Now it is known how the abstract source tree is traversed and in what order the visit functions are called.

```java
ASTParser parser = ASTParser.newParser(AST.JLS3);
parser.setKind(ASTParser.K_COMPILATION_UNIT);
parser.setSource(content.toCharArray());  // set source
ASTNode node = parser.createAST(null);
ASTPrinter.exec(node);
ASTOptimizer.exec(node);
ASTRenamer.exec(node, "de.tu.freiberg.informatik.TestClass2");
String s = org.eclipse.jdt.internal.corext.dom.ASTFlattener.asString(node);
```

Listing 26: Main.java in AST project. (complete code see listing A23)

In lines 52 to 54 in listing 26 the ASTParser will be created. This parses the entire Java file (K_COMPILATION_UNIT) and returns its content as char array containing the text of the Java file. This means the entire Java file will be parsed. The parser starts analyzing the Java file, creating the AST structure of the content and returning the AST root node by calling createAST. The methods ASTPrinter.exec(node), ASTOptimizer.exec(node) and ASTRenamer.exec(node) will print some information of the abstract source tree to the console, delete unused private functions and fields, and change the package and class name of the Java file by manipulating the corresponding AST nodes. After having manipulated the Java AST, Java source code will be created and written into a different Java file by calling ASTFlattener.asString(node). The explanation on how to manipulate Java AST will be given at the ASTRenamer class (see listing 27).

Since the AST nodes should visit the functions to manipulate them, the ASTVisitor class has to be extended as shown in line 14. The static method exec calls CompilationUnit::accept and passes the root AST node to it. This is the starting point of the traversing process. If traversing reaches the PackageDeclaration node, the method ASTRenamer::visit(PackageDeclaration) is invoked and it changes the package declaration name to the wanted one. If the TypeDeclaration node is called (this means the node is the declaration of an interface or a class – see table A3) a test will be done. The check tries to find out whether the class or interface is declared as public to match the name of the Java file later. If the result is positive, the interface or class name will be changed to the desired one. Both visit functions return false, because neither the child nodes of the package declaration nor the type declaration should be traversed. Listening A23 shows the complete example including source code and console output.

Michael von Wenckstern: Web Applications Using the Google Web Toolkit
public class ASTRenamer extends ASTVisitor {

    public static void exec(ASTNode node, String newClassName) {
        CompilationUnit cu = (CompilationUnit) node;
        cu.accept(new ASTRenamer(newClassName));
    }

    public boolean visit(org.eclipse.jdt.core.dom.PackageDeclaration packageDecl) {
        String pName = className.substring(0, className.lastIndexOf(".")));  
        packageDecl.setName(packageDecl.getAST().newName(pName));  
        return false;
    }

    public boolean visit(org.eclipse.jdt.core.dom.TypeDeclaration typeDeclaration) {
        if (Modifier.isPublic(typeDeclaration.getModifiers())) {
            String name = className.substring(className.lastIndexOf(".") + 1);
            typeDeclaration.setName(typeDeclaration.getAST().newSimpleName(name));
        }  
        return false;
    }

   }
}

Listing 27: ASTRenamer.java in AST project.(complete code see listing A26)

General overview of compilation steps

This paragraph summaries the code of the GWT compiler and therefor many explanations are copies from Google’s codes and comments of the package and sub packages of com.google.gwt.dev, especially com.google.gwt.dev.jjs.

Figure 6: General steps of the GWT compiler

Figure 6 shows an overview of the entire compilation process. At the initialization step, command line arguments were tested and passed to the CompilerOptions class (see figure A42 for the command line parameters) and if any parameter is missing then all parameter options will be printed to System.out. A GUI or a normal PrintWriter logger will be created – which displays the output at a given detail (Error, Warn, Info, Trace, Debug, Spam, All). After the logger is created, the function CompileTaskRunner.doRun is called, which starts the other steps of the compilation process, catches all exceptions during the compilation and gives these to the logger. In the first step the compiler also checks once a day if a new version of the GWT API is available and if so it notifies the logger. Later on, all needed modules will be loaded and a working directory for the compilation will be created at System.getProperty("java.io.tmpdir")\textsuperscript{17}. At a later point, a GWT unit cache is loaded which contains compilation artefacts to speed up the compilation process. Opening the unit cache file in a text editor, shows that it is a combination of several source files. In this example it contains 2275 different code files. Figure 7 illustrates

\textsuperscript{17}the folder name was: C:\Users\User Accoutname\AppData\Local\Temp\gwtc1813510714541001888.tmp
the sub steps of the pre compilation process, which will be explained later in more detail. In the step after the pre compilation process, identical permutations are merged together in order to save later one or more permutations and unique ids for the permutations are generated. In the same phase the initialization for the compilation process starts by creating a working factory, which listens for external workers at port 51460 to get the compilation results. This means the compilation permutations are executed by a given amount of workers, which can be set by the --localWorkers flag. Figure 8 illustrates the sub steps of the compilation permutation, which will be described later. The compilation process returns a number of JavaScript artefacts, which will be merged together in the linking step. The Link class uses different Visibility states to determine whether the client needs the generated outputs or if these files are only used for the deploying process on the server.

Figure 7 shows additional details about the pre compilation process. Firstly the compiler looks for all possible rebinds of the declared entry points. These are all the building paths the compiler has to take care of later. Afterwards it searches for all JavaScriptObjectImpl types, which are not often used directly in the Java source code. This is to protect them from being removed in the Abstract Syntax Tree when the dedicated Eclipse compiler compiles the Java project. The compiler will look for correlations in the source files to find out which classes should be included for a defined compilation path.

Now the Eclipse Java development tools (JDT) compiler compiles the Java source code using GWT specific concepts like JSNI and deferred binding to create the JDT AST parse tree. The compiler then looks through a list of compiled units in order to find any errors which occurred during the JDT compilation. After this step the compiler creates raw, unfinished and unlinked AST nodes for types, methods, fields and parameters by mapping JDT AST nodes to these newly created AST nodes and parsing all JSNI source codes. Afterwards the compiler checks for syntactic JSNI errors and aborts the compilation if any have occurred. The compiler records all super classes and interfaces of a given class including this class itself, e.g. checking the class String would return as super classes Object and String and as super interfaces Serializable, CharSequence and Comparable<String>. The compiler creates GWT AST from JDT AST by combining information from JDT type nodes and the type map to generate a JProgram structure and to carry out auto boxing of Java types. After this the compiler can check the GWT AST for semantic JSNI errors and aborts if any occur. The next step is the normalization of Java AST. This contains several sub steps: (1) Complex unboxing of expressions like x++ or x+=3 will be done in two steps, firstly x++ will be converted to x=x+1 and secondly auto boxing will change the result to x=box(unbox(x)+1). (2) All assertions from the AST will be removed to speed up the code. (3) The compiler replaces GWT.create calls with the creating call defined in deferred binding by swapping out GWT.create nodes with JGWTCreate ones. (4) GWT.runAsync will be replaced with a fragment loader, which downloads the JavaScript code when it is needed. (5) An initial loading sequence of split points will be chosen by identifying split points, which must be loaded before other ones. This means the compiler takes care of code dependencies. (6) Entry points will be resolved and non-static ones will be rebounded. (7) The compiler creates a field representing implementations of class literals. Now the normalized Java code will be optimized, which will be explained in the next paragraph. The compiler records all available
rebinds again, as some rebinds could have vanished during the optimization. The pre compilation process finishes creating a unified, non-permutation specific AST using the GWT Java AST.

![Diagram of compilation process]

**Figure 8: General steps of one compilation permutation**

After explaining the pre compilation step, figure 8 gives more information about the compilation process. Firstly the compiler exception class for unexpected and unsupported state of operations is loaded. Later all compiler options for this permutation like `ClientBundle.enableInlining = true` and `compiler.emulatedStack=false` and the unified AST from the pre compilation are loaded. Afterwards the compiler resolves rebinds by inserting permutation-specific deferred binding code. Java AST code will be optimized again with permutation-specific optimization options. Calls to empty super constructors will later be removed. Now the high-level Java tree will be normalized into a lower-level tree, which is more suited for JavaScript code generation.

The code generation is done in several sub steps: (1) The compiler creates functions for single runtime dynamic dispatch and then it matches dynamic dispatches to static ones. This is done if the compiler does not know the object type and so it has no idea what overwritten virtual function should be called. That is why an if statement block is generated. This contains all possible opportunities to call the method depending on the object type. (2) Multi-catch blocks will be merged into a single block, e.g. listing 28 will become listing 29.

```
try {...}
catch (NullPointerException e) {...}  
catch (IOException e) {...} 
```

Listing 28: Multi-catch block

```
try {...}
catch (Exception e) {
  if (e instanceof NullPointerException) {}  
  else if (e instanceof IOException) {...}
}
```

Listing 29: Single-catch block

(3) Problematic type compound assignments (e.g. `long` assignments) will be replaced with a sequence of more simple operations and these will be optimized by the compiler to prevent calculating operations twice, e.g. `x = 1+w; w = 2*(1+w)` will become `temp = 1+u; x = temp; w = 2*temp`. (4) The compiler handles casts from Java type `long` and `long` operations are replaced with calls to the emulation library, because JavaScript one does not support the `long` type. (5) Cast and `instanceof` operations are substituted for the `Cast` class. This is needed because JavaScript is typeless and the `Cast` class contains a `queryId` telling the JavaScript code what type it should be. The `queryId = 0` tells the JavaScript engine it was Java type `Object` and casting will always succeed. (6) The compiler replaces array access and instantiations like `c = new char[3]` with calls to the `Array` class, because JavaScript creates arrays as `c = new Array("Anita", "Ema")`. (7) Java’s equal operator (`==`) will be changed to JavaScript’s identical operator(`===`); but if the equal operator returns the same as JavaScript’s identical operator, then the equal operator will be used in order to save one character each time. More information about JavaScript’s equal and identical operator is available at [Cha06, pp. 80–82].
After the normalization step the compiler will carry out further optimizations by removing globally unreferenced classes, interfaces, methods, parameters and fields from AST and by deleting *JavaScriptObject* single implementations when the implementer is no longer in the abstract source tree. Now the major step creating JavaScript AST from GWT Java AST will be executed. After this the JavaScript AST will be normalized in several sub steps: (1) Semantic JavaScript errors, which were introduced by converting Java AST to JavaScript AST, will be fixed. (2) All unresolved Javascript name references will be resolved. (3) The compiler moves all function definitions to the top of the file, so it does not have to worry about function definitions in blocks. That means lexical scoping can be used instead of dynamic (nested) scoping. An advantage of lexical scoping is that the browser can invoke function calls faster, because it has only to search the function names from top to bottom instead of parsing the complete context. Now the `optimizeJS` function is called in order to optimize the JavaScript code which will be explained in the next paragraph. After this all case labels will be combined with identical bodies, e.g. listing 30 will become listing 31.

```
switch (x) {
    case 0: y = 17; break;
    case 1: y = 17; break;
    case 2: ...
}
```

Listing 30: Uncombined case labels

```
switch (x) {
    case 0: case 1: y = 17; break;
    case 2: ...
}
```

Listing 31: Combined case labels

In the next step the GWT compiler emulates JavaScript stack, providing useful stack traces on browsers which do not offer stack information. The *JsProgram* AST is divided into multiple fragments, because the initial fragment (which is all except for anything called in a callback of `GWT.runAsync` which will be downloadable via `AsyncFragmentLoader.inject`) is sufficient to run all of the program’s functionality. JavaScript AST will be obfuscated in order to decrease download size later. After this the JavaScript AST will be rewritten to handle references from one code fragment to another better. Before generating JavaScript code from JavaScript AST, large `var` statements will be divided into smaller ones, e.g. `var a,b,c,...,x,y,z` becomes `var a,b,c,...,l,m; var n,o,...,y,z`. This is needed because very long `var` statements cause trouble on some browsers. Later on, the compiler creates the permutation properties, a serialized symbol map for allowed remote procedure calls, and the permutation result object containing JavaScript code as bytes. If the --soyc, which is an abbreviation for story of your compile, flag is used, then different information about the compilation process will be added to the permutation result object.

**GWT compiler optimizations**

Almost all Java code optimization is done in the `com.google.gwt.dev.jjs.JavaToJavaScriptCompiler::optimize` function. This method contains a loop, which calls several times the `optimizeLoop` in order to do one optimization step. The number on loop runs depends on the optimization level x: If x is between one and eight, then at most x loop runs will be done. But if the optimization level is equals nine (maximum), then the loop will be executed as long as the `optimizeLoop` will have no optimization effect on the source code. Numerous loop executions are done, because the previous run can unlock better optimizable code for the next one. If the aggressive optimization option has not been disabled by setting the compiler flag `-XdisableAggressiveOptimization`, then the compiler does data flow optimization after the optimization loop.

Figure 9 shows the optimization phases, which are done in the `optimizeLoop` function. All the implementations of the optimization classes can be found in the `com.google.gwt.dev.jjs.impl`
Figure 9: Optimization order in optimizeLoop(), names are the GWT class names performing the optimization phases

Java code pruning means deleting globally unreferenced AST nodes by determining their reachability from the root nodes (entry points) based on class creations with the new operator and function invocations. The pruner will do no local code flow observation, it will only remove classes and interfaces in addition to fields, methods and parameters. This is the most important optimization phase, because it will delete all included but unused GWT library classes. If this step did not exist, then the generated JavaScript code would not be downloadable at all, because the server would transfer all the GWT widgets, which are automatically included, even if these are not used at all. The finalizer detects and marks all nodes that are 'effectively' final; e.g. classes that are not inherited, functions which have never been overridden, and only once assigned variables. The next phase makes final functions to static ones containing the original method’s body and an instance functions delegating to this new static method; e.g. `a.add(b)` will be delegated to `add(a,b)`. The main reason for doing this is to save later the this keyword in the compiled JavaScript code making it shorter. The type tighter substitutes general types like `List` with more specific ones like `ArrayList` in order to reduce `instanceof` checks and dynamic type castings. Examples: final `List foo = new ArrayList();` will become final `ArrayList foo = new ArrayList();` and `Collection bar() { return new LinkedHashSet(); }` will become `LinkedHashSet bar() { return new LinkedHashSet(); }`. The main issue doing this optimization is that the next phase "method call tightening" can remove useless generated run-time dispatch code for virtual function invocations. This means the compiler knows the concrete class and so it is able to invoke the specific method call, now. This operation also sets the type of a variable to `null`, if it was never initialized, or only once `null` assigned and was not reassigned. This allows the compiler to do further optimizations. "Method call tighten" replaces polymorphic method calls to more specific ones, e.g. `List foo = new ArrayList();` will become `ArrayList foo = new ArrayList();` by type tightening and so instead of `List::add` the function `ArrayList::add` is called. This means no JavaScript single dispatch replacement code must be generated. The dead code elimination step does even more than just eliminating code - table 6 shows the different operations.

The next paragraph gives further explanations of table 6. In (1) simple expressions like `null == null` occur, because the type tightening also sets variable types to `null`. In (8) nearly all `if` and `else` keywords are removed in order to get better compressed JavaScript code later. (9) Substitutes post operations with pre operations to speed up runtime, because the browser can save one copy operation of the variable. The "method inline" phase inserts function bodies containing no more than two lines of Java code and no other method invocations. This way the application speed can be increased, because the JavaScript interpreter does not have to jump to the methods and in most cases embedding maximal two code lines into multiple places is shorter than the extra method declaration plus the calls to it. The "same parameter value optimizer" substitutes
Table 6: Dead code elimination grouped in different steps

| (1) updating logical expressions | if (true && isWhatever()) -> if (isWhatever())  
|                           | if (false && isWhatever()) -> if (false)  
|                           | if (true || isWhatever()) -> if (true)  
|                           | if (false || isWhatever()) -> if (isWhatever())  
|                           | null == null -> true  
|                           | if(!a == b) -> if(a!=b)  
|                           | null != null -> false |
| (2) shorten xor expressions | true ^ x -> !x  
|                           | false ^ x -> x  
|                           | y ^ true -> !y  
|                           | y ^ false -> y |
| (3) shorten numerical expressions | j + 0 -> j, 0 + j -> j, j - 0 -> j, 0 - j -> -j  
|                           | j * 1 -> j, 1 * j -> j, -1 * j -> -j, j / (-1) -> -j  
|                           | j * 0 -> 0, 0 * j -> 0, j / 1 -> j, j / (-1) -> -j |
| (4) shorten assignments | a = 3, b = 3 -> a = b = 3 |
| (5) concat strings | s = "Hallo " + "Tom" -> s = "Hallo Tom" |
| (6) removing blocks with no effect | if(x == 0) { y = 0; } -> if(x == 0) y = 0; |
| (7) removing useless loops | do { ... } while(false); -> {...}  
|                           | for (X; false; Y) {...} -> Y;  
|                           | while(false) {...} -> {} |
| (8) remove useless and shorten if code | if(true) x = 3; else x = 4; -> x = 3;  
|                           | if(false) x = 3; else x = 4; -> x = 4;  
|                           | (cond ? true : else) -> cond || else  
|                           | (cond ? false : else) -> !cond && else  
|                           | (cond ? then : true) -> !cond || then  
|                           | (cond ? then : false) -> cond && then  
|                           | (!cond ? then : else) -> (!cond ? else : then)  
|                           | if (!cond) foo else bar -> if (!cond) bar else foo  
|                           | if(x) return 3; else return 4; -> return x ? 3 : 4;  
|                           | if (x) s1 else s2 -> x ? s1 : s2;  
|                           | if (x) s1 -> x && s1; |
| (9) replacing post operator with pre operator if possible | x++ -> ++x, x -- -> -x |
| (10) optimize switch blocks | switch(x) { case 1: { } case 2: { } case 3: { s1 } }  
|                           | -> switch(x) { case 3: { s1 } } |
| (11) deleting catch blocks whose exception type will never be thrown and prune empty try statements |
| (12) static evaluation of literals | s = 3 + 8 -> s = 11  
|                           | s = true && false -> s = false  
|                           | -(~x) -> x |
the method’s parameters with literals, which are used in method calls in the function body. Listing 32 shows an example code before this optimization phase and listing 33 after. In line 3 the true literal substituted the log parameter, because the execute function was always called (see lines 8 and 9) with log equals true. The useless parameter log and the if condition will be deleted later. This is the reason why the optimizeLoop is called several times as mentioned above.

```java
void execute(., ., boolean log) {
  . . .
  if (log) {
    logger.log(.
  }
  . . .
  execute(a, b, . . ., true);
  execute(x, y, . . ., true);
}
```

Listing 32: Same parameter value optimizer: before

```java
void execute(., ., boolean log) {
  . . .
  if (true) {
    logger.log(.
  }
  . . .
  execute(a, b, . . ., true);
  execute(x, y, . . ., true);
}
```

Listing 33: Same parameter value optimizer: after

The "enum ordinalizer" phase replaces enum constants with the corresponding ordinal values by changing their field constants to integer variables. The enum class will be removed later. Listing 34 displays the code before this optimization phase and listing 35 (compare lines 7 and 8) afterwards.

```java
public enum DAY {
  SUNDAY, MONDAY, TUESDAY,
  WEDNESDAY, THURSDAY,
  FRIDAY, SATURDAY
}

public static void main(String[] as) {
  Day firstDay = new EnumTest(DAY.MONDAY);
  Day thirdDay = new EnumTest(DAY.WEDNESDAY);
}
```

Listing 34: Enum ordinalizer optimizer: before

```java
public enum DAY {
  SUNDAY, MONDAY, TUESDAY,
  WEDNESDAY, THURSDAY,
  FRIDAY, SATURDAY
}

public static void main(String[] as) {
  Day firstDay = new EnumTest(1);
  // Day.SUNDAY = 0
  Day thirdDay = new EnumTest(3);
}
```

Listing 35: Enum ordinalizer optimizer: after

After the optimizations in the optimizeLoop have been explained, the next paragraphs describe the dataflow optimizer. ‘Dataflow optimization is the code improvement by transformations which are justified by assertions starting with the weakest one (true) and computing strongest postconditions. Listing 36 shows constant propagation and folding done with dataflow analysis.

```java
{ true }
  x = 9;
  { x == 9 }
  y = 3;
  { x == 9 && y == 3 }
  z = x - y;
```

Listing 36: Simple dataflow analysis example

This means in the assignment z = x - y the assertion x == 9 justifies replacing x with 9, this means z = 9 - y. The other assertion y = 3 justifies substituting 3 for y, as the result we are getting the assignment z = 6. This means the aim of dataflow optimization is to find valid assertions allowing code improving transformations. Assertions are characterized as dataflow facts relating to traditional program logic. A data flow fact is
either a program state or continuation assertion. A lattice is a set of dataflow facts. To ensure that the analysis ends, it is enough if every fact has only finitely different facts above it. Mostly a different lattice of dataflow facts is used by different analyses.

A continuation assertion is an assertion about paths from a specific program point to a procedure end, or some other kind of ending; also known as backward dataflow analysis. Information about forward dataflow analysis can be found at [NR08, p. 3]. An edge in a control flow graph represents a program point. Edges connect nodes representing an assignment, a label or a control transfer. A transfer function computes dataflow facts on outgoing edges of a node out of incoming edges.” [NR08, pp. 1-3] The aim of this short introduction to dataflow optimization is to allow a better understanding of the graph interface (public interface Graph<

```java
public interface Graph<NodeType, EdgeType, TransformerType> {
    public TransformerType getTransformer();
    public EdgeType getEdge();
    public NodeType getNode();
}
```

The integrated analysis interface contains a reference to the integrated flow function, which either interprets the node or produces node transformations based on already computed assumptions. The already computed assumptions are stored in the interface as map (AssumptionMap) combining assumption and edge types; these assumptions are quasi the input and output of the integrated flow function. To give an example, listing 37 shows the source code of unreachable analysis.

```java
public class UnreachableAnalysis implements IntegratedAnalysis<
    CfgNode<?>,
    CfgEdge, CfgTransformer, Cfg, UnreachableAssumptions> {

    private static final UnreachableIntegratedTransformationFunction
        INTEGRATED_FLOW_FUNCTION = new
        UnreachableIntegratedTransformationFunction();

    public IntegratedFlowFunction<CfgNode<?>, CfgEdge, 
        CfgTransformer, Cfg,
        UnreachableAssumptions>
        getIntegratedFlowFunction() {
        return INTEGRATED_FLOW_FUNCTION;
    }

    public void setInitialGraphAssumptions(Cfg graph,
        AssumptionMap<CfgEdge, UnreachableAssumptions> assumptionMap)
    {
        AssumptionUtil.setAssumptions(graph.getGraphInEdges(),
            UnreachableAssumptions.REACHABLE, assumptionMap);
        AssumptionUtil.setAssumptions(graph.getGraphOutEdges(),
            UnreachableAssumptions.UNREACHABLE, assumptionMap);
    }
}
```

Listing 37: Source code of UnreachableAnalysis.class in GWT Software Development Kit (SDK) 2.4 in gwt-dev.jar (package com.google.gwt.dev.jjs.impl.gflow.unreachable)

Cfg is the abbreviation for control flow graph. The Cfg class implements the Graph class and is the control flow representation for the entire gflow framework. This class contains array lists for the nodes as well as edges coming in and going out of the graph. It also contains a transformer function changing the AST structure of this graph. CfgNode is the class type of the nodes in the Cfg class. This class has two collections: one for the edges, which are coming into the node, and
one for the edges which are going out. The template parameter of this class extends the JNode
type, which is the base class for all GWT AST nodes. For general understanding, it is enough
to say that the CfgNodes of the Cfg graph are a subset of all GWT AST nodes. CfgEdge is
the class type of the edges in the Cfg class containing a start node and an end node of one edge.
The UnreachableAssumptions implements the Assumption<UnreachableAssumptions> inter-
face and acts like an enum class having two fields REACHABLE and UNREACHABLE.
The actual implementation of the transformation can be found in the UnreachabeInteg-
atedTransformationFunction class. Listing 38 shows the source code of this class. With the

```java
public class UnreachableIntegratedTransformationFunction implements

  IntegratedFlowFunction<CfgNode<?>, CfgEdge, CfgTransformer>,

  Cfg,

  UnreachableAssumptions>

public Transformation<CfgTransformer, Cfg>

  interpretOrReplace(CfgNode<?> node, Cfg graph,

  AssumptionMap<CfgEdge, UnreachableAssumptions> assumptionMap)

  {

    UnreachableAssumptions in = AssumptionUtil.join(

      graph.getInEdges(node), assumptionMap);

    if (UnreachableAssumptions.isReachable(in)) {

      AssumptionUtil.setAssumptions(graph.getOutEdges(node),

        UnreachableAssumptions.REACHABLE, assumptionMap);

      return null;

    }

    if (node instanceof CfgNopNode) {

      AssumptionUtil.setAssumptions(graph.getOutEdges(node),

        UnreachableAssumptions.UNREACHABLE, assumptionMap);

      return null;

    }

    return new DeleteNodeTransformation(graph, node);
  }
```

Listing 38: Source code of UnreachableIntegratedTransformationFunction.class in GWT
SDK 2.4 in gwt-dev.jar (package com.google.gwt.dev.jjs.impl.gflow.unreachable)

join operation in lines 7 and 8 the maximum of all edges coming into this node are calculated
(max(REACHABLE, UNREACHABLE) = REACHABLE). If the input maximum is reach-
able, then all output edges are reachable (lines 10 until 13). If the node carries out no operation,
e.g. containing an empty body, then all output edges are unreachable (lines 15 to 18). If the max-
imum is unreachable and the node is not a no-operation node, then the DeleteNodeTransfor-
mation class tries to delete unused statements in line 20. The DataflowOptimizer class executes
ConstantsAnalysis, CopyAnalysis and LivenessAnalysis besides UnreachableAnalysis.

Constant analysis replaces constant local variables and constant parameters; constant prop-
agation and folding (see listing 36) are parts of this analysis. Copy analysis works are similar to
constant analysis, except that it is not allowed for variables to be equal in assertions. Listing 39
shows such an example. This means the compiler will replace \( z = 5 + y \) by \( z = 5 + x \) and will delete
the useless assignment \( y = x \) later. The analysis is called so, because the compiler recognizes that
one variable is just a copy of another one and so the optimizer will substitute the copy with the
original variable. In liveness analysis the compiler calculates at each program point the life of

Michael von Wenckstern: Web Applications Using the Google Web Toolkit
variables, which is the timespan where a variable may be potentially read before its content will change. The life of variables is used to remove useless assignments. This analysis is a backward dataflow. To get a better understanding listing 40 shows an example and figure 10 the corresponding control flow graph. Since the node b=0 contains no lines to other nodes, the lifespan of the variable b in line 2 is zero. As a result the optimizer will delete this node. The variables a and c have at least two life ranges, e.g. the first lifespan of a is from line 1 to line 4 and the second one is from line 6 to line 7 or line 4 (if it is extended by the loop). Any executed jump creates a new live range of the variable a in line 6. The demonstrated liveness example is a modification from [Pro04, pp. 4-5]. Exact definitions and an algorithm to determine the liveness of variables can be found at [Pro04, pp. 7-13].

As mentioned at the beginning of this paragraph, most of the optimizations are done in the optimize function. But one more Java optimization step, which removes all calls to super constructors with empty bodies, is executed in the compilePermutation function after the optimize function has been called.

After explaining the Java AST optimization steps in great detail, the JavaScript AST optimizations will be only touched on. Firstly the JsStaticEval (JavaScript static evaluation executor) will do the same optimizations on JavaScript code as the dead code elimination step (see table 6) does on Java code. Secondly, the JsInliner optimization is running and it can be compared with the MethodInliner for Java code. Lastly the JsUnusedFunctionRemover will delete JavaScript methods, which are not referenced in the program. All the optimizations mentioned can be found in the optimizeJs function in the JavaToJavaScriptCompiler class.

The explanation of the GWT compiler steps is finished, it is now known what the compiler does, why the compilation process does several permutations and why compiling a GWT ap-

---

If it is not obvious at the first look, think a is an array then the code in listing 40 would be: a[0] = 0; index=1 (line 1), b = a[index-1] + 1 (line 4), a[index++] = b + 2 (line 6). And so a[0] until a[array length] are the different live ranges.
Application needs so much time. Testing a GWT application can also be done in the developer mode, which does not invoke the GWT compiler, in order to save time (for more information see appendix A 1).

### 3.4 Java Runtime Environment Emulation

The Java Runtime Environment Emulation (JREE) is a library emulating the most commonly used part of the real Java Runtime Environment (JRE). The emulated java source files can be found in the gwt-user.jar library at com.google.gwt.emul. Since the package explorer shows only *.class files of java archives, the gwt-user.jar archive must be opened with WinRAR or some similar program in order to change them. Figures A43, A44 and A45 show the UML diagrams of the JREE. They list all the JREE classes of GWT 2.4, because it is useful to know what classes are allowed to be used. The tricky thing is, that the development mode uses the standard Java JRE, because the code will be interpreted by the GWT code server and will not be compiled using the GWT JREE. As a result, JRE classes, which do not belong to the JREE, can be used in development mode. These classes like `java.util.GregorianCalendar` work in the web application running in the development mode the same way as they would work in a normal Java program. Listing 41 and figure 11 show an example of this. Only an error message like "Errors in 'file:/C:/GWT/workspace/DA_JREE/Calendar/src/de/tu_freiberg/informatik/vonwenckstern/client/Today.java': [ERROR] [de.tu_freiberg.informatik.vonwenckstern.ImageViewer] - Line 8: No source code is available for type java.util.GregorianCalendar; did you forget to inherit a required module?" indicates that the web application does not use a JREE class.

```java
20  Window.alert(Today.getToday());
21  
22  public static String getToday() {
23       GregorianCalendar calendar = new GregorianCalendar();
24       String s = calendar.get(Calendar.DAY_OF_MONTH) + "." +
25           Integer.toString(calendar.get(Calendar.MONTH) + 1) + 
26           "." +
27           calendar.get(Calendar.YEAR);  
28       s += "\actual\_week:" + calendar.get(Calendar.WEEK_OF_YEAR);  
29       return s;
```

Listing 41: Simple example code for using no JREE class

See listing A27 and A28 for the complete source code.

Ignoring this error causes GWT to abort the compilation process. Since the compiler does not have any source code for the `GregorianCalendar` class, it will show an error list containing a lot of unresolved fields and methods of this class. The JREE source files show, that the basic code is written with JSNI (see section 3.3.1 for more information about JSNI, `JavaScriptObject` and `GWT.create`). This is why the Java JRE functions sometimes behave a little differently to the compiled JavaScript JREE functions. This phenomenon will be explained at the JSNI function `String::split(String regex, int maxMatch)`. This means that the regular expression parameter will be interpreted in the web browser as JavaScript regular expression, since JSNI replaces Java regex calls with JavaScript ones. The problem is that the Java regular expression is slightly

---

19If GWT has been installed via the GWT plugin as shown in appendix A 1, this file is located under `<eclipse>/plugins/com.google.gwt.eclipse.sdkbundle_2.4.0.vxxx/gwt-2.4.0/ gwt-user.jar`
different from the JavaScript one. The two online regular expression tester [Goy] for JavaScript and [Reg] for Java help to figure out the difference.

The next paragraph explains the main differences. The `\` sign means in Java that a special class will be negated in order to match; in JavaScript it signifies that the string must match the regular expression from the beginning on. Java supports quote matching with `\Q ... \E`, but JavaScript does not. Java matches strings only if they begin with the first regular expression character and end with the last one. In JavaScript this behavior can be forced by starting the regular expression with `\` and ending it with `$`. It is advisable to avoid JavaScript specific regular expressions like `$', which allow the replacement of characters, to have the same result in compiled and debug mode. Table 7 compares Java and JavaScript regular expressions.

Table 7: Examples to show the difference of `String::match` in the Java vs. JavaScript world.

<table>
<thead>
<tr>
<th>Regular expression</th>
<th>Input string</th>
<th>Java matches</th>
<th>JavaScript match</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>\d+</code></td>
<td>a123b</td>
<td>no</td>
<td>yes</td>
</tr>
<tr>
<td><code>\d+</code></td>
<td>123</td>
<td>yes</td>
<td>yes</td>
</tr>
<tr>
<td><code>\d+</code></td>
<td>a123b</td>
<td>no</td>
<td>no</td>
</tr>
<tr>
<td><code>\d+</code></td>
<td>123b</td>
<td>no</td>
<td>yes</td>
</tr>
<tr>
<td><code>\d+$</code></td>
<td>123b</td>
<td>no</td>
<td>no</td>
</tr>
<tr>
<td><code>\d+$</code></td>
<td>123b</td>
<td>no</td>
<td>no</td>
</tr>
</tbody>
</table>

Listing 42 displays a quote function for regular expressions working on both Java and JavaScript. The dissimilarities between the JRE and JREE have been explained in more detail

```java
1. public static String quoteStringForRegex(String str) {
2.     String res = "";
3.     for (int i=0; i<str.length(); i++) {
4.         String hex = Integer.toHexString(str.charAt(i));
5.         res += \x" + (hex.length() < 2? "0":")" + hex;
6.     }
7.     return res;
8. }
```

Listing 42: Source code of a quote function for regular expressions in JS and Java e.g. "\x64" means there should be used the sign with the ASCII hex code 64, which is "d"

to help understand some irregular occurrences during the GWT development.

The above paragraph could create the impression that the JREE classes are not very helpful, because of the trouble which can occur. But an active Java developer will be pleased to use the `String`, `ArrayList` and `HashMap` classes, because in most cases they work the same way as in the JRE. [Ros03] gives a tutorial on how to emulate missing JRE classes in GWT.

The answer to the question whether GWT provides the most important Java classes can only be a partial yes. The main reason why the question is not answered with a clear yes is that some very important classes like the Calendar emulation are missing and this results in an extensive usage of the depreciated `Date` class.

### 3.5 Widgets and Panels

#### 3.5.1 Overview of GWT Widgets

The showcase in subsection 3.1 introduced the most important GWT widgets. This subsection gives a hierarchical overview of the most relevant GWT widgets. The next subsection describes how these components handle user inputs.

Michael von Wenckstern: Web Applications Using the Google Web Toolkit
The book GWT in Action gives a nice definition for widgets: "Widgets are the visible components of a GWT application that a user can see on the browser page." [HT07, p. 110]. Widgets are the analogue to the Java Swing user interface components like JButton or JTextField. A list of all GWT widgets can be found at [Goo10d]. As illustrated in figure 12, all widgets inherit from the UIObject. This class wraps HTML DOM properties (see section 2.5 for information) in such a way, that they can be manipulated in Java code. The most important methods of the UIObject class are addStyleName(String) to add a new CSS class to this widget, getAbsoluteLeft and getAbsoluteTop to get the absolute position in pixels of the element in the web browser, getOffsetHeight and getOffsetWidth returns the size in pixels of the displayed object, isVisible tells whether the user can see the widget, and the getElement method handles the corresponding DOM object to manipulate the HTML DOM directly by adding or removing DOM nodes. More information about modifying the HTML DOM with GWT can be found in the API of the com.google.gwt.dom.client.Node class at [Goo10c].

Since there is no information about the operations of a class during JavaScript runtime, the widgets implement many interfaces describing the methods of the widgets. A check with Java’s instanceof operator tells whether the widget contains a specific method. For example the Panel widget implements the HasWidgets.ForIsWidget interface, that means it supports the operations add and remove to add or delete widgets. The numbers behind the classes in figure 12 represent the interfaces, which the widgets implement. The corresponding interface with all important methods can be found in figures A46 and 19. The last image contains the events which support the widget. GWT events and the corresponding handler interfaces will be discussed in the next subsection.

The last picture shows that the Widget class extends the UIObject and implements EventListener and the HasAttachHandlers interface to support low-level browser events and notifications. These are fired when the object is being attached or detached to the browser’s document. The MenuItem class generates a unique id in the document DOM model in order to support
ARIA (Annotations for assistive technology products). It is not a widget, because creating the entire menu of the given menu items and handling the events is done by the MenuBar widget.

The next paragraph gives more details about the CellWidget. As mentioned before, normal widgets extend the UIObject class, which means all the widget properties are set by DOM manipulation. And cell widgets are "high-performance, lightweight widgets composed of Cells for displaying data" [Goo10d]. These widgets are used in tables, trees and lists. The rendering process is so fast, because it generates a HTML string with all the properties of the widgets and their children. This generated string is set to the DOM model's property innerHTML. Instead of using var div = document.createElement('div'); div.width = 200; var span = document.createElement('span'); span.className = 'red'; span.appendChild(document.createTextNode('Error')); div.appendChild(span); document.getElementById(parent).appendChild(div), which needs seven DOM manipulations, cell widgets need only one DOM manipulation with the following code var html = "<div width='200'><span class='red'>Error</span></div>"; document.getElementById(parent).innerHTML = html. The CellWidget class is a wrapper widget, which takes a lightweighted cell widget and turns it into a normal widget. This way cell widgets can be reused outside a CellTable. This class can also be used to create widgets which the browser can render quickly. This is the reason why some class names like ButtonBase are listed twice in the UML diagrams. The ButtonBase class extending the CellWidget generates light weighted buttons, and the ButtonBase class extending the FocusWidget produces heavy weighted DOM buttons with more properties.

The standard GWT widgets can be divided into four types: Label, FocusWidget, Composite and Panel. Figure 13 shows the hierarchy of the LabelBase class. Label widgets display information to the user. The Label class becomes a <div></div> tag in the HTML document and the InlineLabel class becomes a <span></span> tag.

FocusWidgets (figure 14 shows the hierarchy) are widgets which can receive user inputs. Nearly all of them are used in forms to collect user information. Most of the widgets are Java classes for different HTML <input> types. An example should show what pages can be created with these widgets. Listing A29 and figure A47 display the complete example.

The RichTextArea widget shows formatted (bold, underlined, italic, colored) text. The method setHTML(String) sets the styled text. In this example the HTML string "<b><u>GWT</u></b> stands for <i>G</i>oogle <i>W</i>eb<i>T</i>oolkit." was passed as parameter. This results in the following output: "GWT stands for Google Web Toolkit." The tags u, b, i are abbreviations of underlined, bold and italics. The RadioButton widget takes as constructor two parameters: the first one is the group name and the second one is the text displayed after the radio button. Since this class extends CheckBox implementing the HasValue<Boolean> interface, the function setValue(true) selects the button. The PushButton widget accepts as parameter either a string or an image object. If a string value is passed, then
the button displays normal text; but otherwise it draws an icon. In this example the national flag of Germany: Image im = new Image("http://upload.wikimedia.org/wikipedia/...); new PushButton(im) was passed as parameter. The most important method of the ListBox widget is addItem to add new selectable options. The ListBox appears as drop-down list, if the parameter 1 is set to the function setVisibleItemCount(int); otherwise it displays the number of visible items. The classes Audio, Video and Canvas are created by calling the static method createIfSupported, as older web browsers do not support the new HTML5 tags. If the browser does not support the new HTML elements, then this function will return null. Both Audio and Video widgets support setting the source by either calling the setSrc(String) or the addSource(String, String) method. The first function should only be invoked if every browser (Chrome, Firefox, Internet Explorer, Safari, ...) supports the specified file type. Otherwise the second method should be used, because it allows the specification of different file formats. This gives the browser the opportunity to select the URL to the media type, which it supports. The media control bar, which allows the user to start, stop and pause the audio or video playback, can be enabled by invoking the method setControls(true). After the Canvas object has been initialized, the line Context2d context = canvas.getContext2d() creates the draw context. A function call similar to context.setFillStyle(CssColor.make(255, 0, 0).value()) sets the drawing color of text and different shapes. The method rect(int, int, int, int) draws a rectangle and takes the start point as the first two parameters and the size as the last two. The function text(String, int, int) prints text to the draw context and accepts the text as the first and the position as the last two parameters.

The difference between the TextArea and the TextBox is that the first one accepts line breaks and the last one does not. This means the TextArea widget allows the user to input multiple lines.

Composite widgets can wrap one or more widgets. Figure 15 shows the DateBox widget having a TextBox in the top and a PopupPanel, which contains a DatePicker, on the bottom. GWT ships many standard composite widgets to the developer. Figure 16 displays the hierarchy. The example shown in figures A48, A49 and listing A30 introduces these widgets. The NotificationMole class creates a popup information display. The information shown to the user is set by the method setMessage(String). If a number greater zero has been set to setAnimationDuration(int), then the popup needs so much time in milliseconds to show up completely. During the appearance process the information will become visible from top to bottom. CaptionPanel is a normal panel, which contains other widgets with a HTML header text, which is the first parameter in the constructor. DateBox (see figure 15) works like a ValueBoxBase widget, which
Figure 15: DateBox composite contains TextBox, PopupPanel and DatePicker widgets

Figure 16: Composite widget class hierarchy; source: API of GWT 2.5.0 RC 2

Figure 17: The own Composite widget
lets the user enter a date value. ValuePicker is comparable to the non-dropdown ListBox. The only difference is that the operation setAcceptableValues(Collection) sets the possible values. ValueListBox is similar to the dropdown ListBox. But both widgets have an advantage over the normal list box, because it is possible to specify a value renderer interpreting the list data. The DisclosurePanel is a panel with a header, which shows and hides its body content after the user has clicked on the header. As default the body part is not visible; passing true to the setOpen(boolean) method makes the body visible. The CellTree works like a Windows Explorer tree. It shows the parent’s children items after clicking on it. This class needs as first constructor parameter a TreeViewModel containing two methods getNodeInfo(T) and isLeaf(Object). The first function returns the children items of a given parent item and the other one returns true, if the parent item has no children to display. CellTable widget is used to present large data to the user in a table form. The addColumn(Column, String) operation adds a table column to this object. The first parameter object needs to implement the getValue(T) method of the abstract Column class, which returns the value contained in this column from a given record data. After all the table columns have been defined, the row data (=different records) can be set to the table. This is done by invoking the table’s setRowData method, and passing the data as first argument. The CellList widget displays its data as list. The SimplePager object can control the data range which is displayed in the web browser, of either the CellList or the CellTable widget. The connection between the pager and the cell widget is done by passing the cell widget as argument to the pager’s setDisplay(HasRows) function. The StackPanel shows all the children headers but only one body widget at once. Similar to the DisclosurePanel, the children’s body part can be made visible by clicking on its header. The TabPanel works the same way as the StackPanel. The only difference is the appearance: the TabPanels headers are horizontally aligned and always above or below the selected body part. In contrast the StackPanel’s headers are vertically aligned and the visible body part can be located between two headers. The SuggestBox auto completes words while their initial letters will be typed. The MultiWordSuggestOracle contains the recommendation for the auto complete and is the only constructor parameter of this widget.

```java
class LoginComposite extends Composite {
    private TextBox name = new TextBox();
    private PasswordTextBox pwd = new PasswordTextBox();
    private Button btn = new Button("Login");

    public LoginComposite(String defaultName) {
        name.setValue(defaultName);
        FlexTable tbl = new FlexTable();
        tbl.setText(0, 0, "Name: ");
        tbl.setWidget(0, 1, name);
        tbl.setText(1, 0, "Password: ");
        tbl.setWidget(1, 1, pwd);
        tbl.setWidget(2, 1, btn);
        // initWidget must be always in constructor
        initWidget(tbl);
    }
}
```

Listing 43: Example project for own login composite widget

Listing 43 and figure 17 demonstrate how to create a login composite widget. It contains a TextBox, one PasswordTextBox and a Button widget. Firstly, the widget extends the Com-
posite object. Secondly, the widget view will be built by adding several other widgets to the table in the same way they have been added to any application view. Despite adding the FlexTable to the RootPanel, it will be inserted into the composite widget by calling the initWidget(Widget) method inside the composite's constructor.

Panels are widgets containing one or more other widgets. These are used to structure the layout of a website. Figure 18 gives an overview of the different panel types. As always this paragraph starts with an example (see listing A31). Figure A50 illustrates the Panel widgets in action. FlexTable user interface component creates a table supporting cell merging. New cell data can be added to the object by either calling setText(int row, int column, String text) or setWidget(int row, int column, Widget w). The code line DOM.styleAttribute(formatter.getElement(row, col), "border", "1px solid black") makes the cell lines hidden by default visible. After the cells distance has been set to zero by calling setCellPadding(0) and setCellSpacing(0), a nice table grid has been created. The FlexTable does not really support cell merging, but it can be emulated by:

- displaying one cell over several rows and columns. The methods setRowSpan(int row, int column, int rowSpan) and setColSpan(int row, int column, int colSpan) of the table’s FlexCellFormatter class (FlexTable.getFlexCellFormatter()) will do this work.
- removing the cells, which should become merged together with the expanded ones. This is done by calling the table’s removeCell(int row, int column) method.

The difference of the HeaderPanel widget to the CaptionPanel one is that the first one allows setting a header widget to the header part instead of only plain HTML text. The header widget may even contain other widgets. The HeaderPanel also allows setting a footer widget. The
advantage of the HTMLPanel is that the container layout can be set directly as constructor argument. Afterwards the widgets will be inserted into given div-id place inside the container. This is done by calling HTMLPanel's add(Widget widget, String divId) method. The FlowPanel just creates a \texttt{<div>}/\texttt{/div}> environment and inserts every added widget into it, this means the floating layout is handled by the web browsers like line breaking and overflowing. DockLayoutPanel and DockPanel behave the same, the only difference is that the DockLayoutPanel generates its layout by using HTML div elements and the DockPanel uses a HTML table. The functions addNorth(Widget widget, double size), addSouth(Widget widget, double size), addWest(Widget widget, double size), addEast(Widget widget, double size) or add(Widget) add the widgets into the upper, lower, left, right or center part of DockLayoutPanel. The add(Widget widget, DockPanel.DockLayoutConstant direction) method inserts the widget into the DockPanel. The second parameter controls the place where new widgets will be inserted. The HorizontalPanel widget adjusts its children in a line next to each other. The VerticalPanel places its children in a column one below the other. ScrollPanel widget automatically creates scrollbars, if the content of its child widget is larger than the panel's screen size. FormPanel component wraps its child into a HTML \texttt{<form>}/\texttt{</form>} tag. The method submit sends the formula data to the URL specified as parameter in the setAction(String URL) function. DialogBox widget creates an information window, which can be moved around in the HTML website. The method setText(String text) sets the displayed text. A Button or any other widget can be added to the dialog by calling the setWidget(Widget) function. If the DialogBox should act like a modal window, then true has to be passed to the setGlassEnabled(boolean) method.

This section showed that there are a lot of GWT widgets. These ones, together with the widgets of other third party libraries like the GXT one, are an equivalent substitute for every Swing user interface component. Since GWT does not compile byte code to JavaScript, the source code for every widget is available. That makes it easier to create customized widgets by extending the existing ones. This subsection answered one of the two important questions as to whether the GUI components in GWT are equivalent to the Swing ones in a clearly positive way.

### 3.5.2 Event handlers in GWT Widgets

Event handling in GWT works very similarly to event listening in Swing. Both of them use the delegation model:

1. Interested listeners register their class to the object, which should trigger the event. This causes the listener to be added to a subscription list.
2. When the state has changed, the source class generates and fires an event containing the actual state.
3. Now every listener in the subscription list for this event type receives the event. The listeners are called synchronically one after another.
4. Finally the implementation method of the registered class is invoked, and so the listener can start processing the event.

To receive events in GWT the following things have to be done concretely:

1. Implement the handler interface for the event, which should be received.
2. Pass the handler reference to itself or to the widget to add it to the subscription list of the given event type.

Figure 19 shows the most important event handlers, which should be overridden in order to receive the events. Listing 44 illustrates that event handling can be done very intuitively in
Button btn = new Button("Click Me");
btn.addClickHandler(new ClickHandler() {
    @Override
    public void onClick(ClickEvent event) {
        // handle the click event
    }
});

Listing 44: Very simple example of registering a ClickHandler to receive Button click events

GWT. On the surface many anonymous inner classes could be used to receive all the click events from several buttons. However this would result in a creation of a large number of separate ClickHandler objects and the result would be a need of too much memory. The better version is to create just one ClickHandler instance and add this object to every Button's subscription list. Since every GWT event extends com.google.gwt.event.shared.GwtEvent<H extends EventHandler> it inherits the getSource method, which returns the widget which fired the event. Listing 45 displays the correct Java code for handling click events of many buttons.

Button btn1, . . . , btn99;
final ClickHandler clickHandler = (new ClickHandler() {
    @Override
    public void onClick(ClickEvent event) {
        // we now that we registered this handler only to
        // Button classes
        Button sender = (Button) event.getSource();
        if (sender == btn1) {
            // process ClickEvent from btn1
        } else if (sender == btn99) {
            // process ClickEvent from btn99
        }
    }
});
btn1 = new Button("Button 1");
btn1.addClickHandler(clickHandler);

... 
btn99 = new Button("Button 99");
btn99.addClickHandler(clickHandler);

Listing 45: Example how to handle click events of many buttons

Like the more complex EventHandler example in listing A32 and figure A51 the class containing the buttons implements the ClickHandler interface and the event registration is done by calling addClickHandler(this).

Some components like the Label widgets do not fire keyboard events. In this case the widget has to be wrapped inside the FocusPanel, and this panel fires keyboard events. A widget will only fire the keyboard if it contains the input focus.

This subsection finishes by answering the second important question as to whether the event handling is as powerful as in Swing. Even through GWT event handling is very similar to the Swing event listening, it cannot handle as many events as the Java Swing library. This limitation is the result of the stricter security issues which a JavaScript program has to deal with in comparison to a normal desktop application. For example a web application does not have any access to the Windows clipboard, and so the data must be extracted from a contenteditable div element. Section 7 shows how to write data to the clipboard and how to read pasted content. Another drawback of JavaScript and GWT is that no drag and drop download event exists. It
Figure 19: General handler interfaces which implement the widgets to listen to special events; source: API of GWT 2.5.0 RC 2
is possible to upload files per drag and drop, but until now files cannot be downloaded per drag and drop. Without the security and not available JavaScript functionality issues, the second important question can be answered with yes. But if the web application needs to write binary data into the clipboard, if it needs hard disk access, or if the user should be able to download several files at once, then there is no equivalent GWT functionality available. This means in such a case it is not possible to create a web application which has the same user comfort as the equivalent desktop program.

### 3.5.3 Manipulating browser's DOM with GWT DOM class

Section 2.5 showed that programs written in JavaScript mostly manipulate the HTML DOM structure to change the website’s layout. Because of the different DOM browser specifications, GWT provides many widgets (see section 3.5.1 to get an overview) wrapping up this functionality. But sometimes it is necessary to have direct access to the HTML DOM model. Luckily GWT provides an almost browser independent DOM (API is available under [Goo10a]) class for manipulating HTML directly. As mentioned in the previous part of this section, every widget extends `UIObject` and inherits the `getElement` method. This method returns the underlying DOM element node. For example the function `widget.getElement().getStyle()` accesses the element’s style properties. These can be manipulated as shown in listing 46. Listing 47 shows how the restyling can be done in a more compact way using the GWT DOM class.

```java
RichTextArea rt1 = new RichTextArea();
Style style = rt1.getElement().getStyle();
style.setBorderColor("blue");
style.setBorderStyle(Style.BorderStyle.SOLID);
style.setBorderWidth(3, Unit.PX);
```

Listing 46: Manipulating the widget’s border style with GWT Style class

```java
DOM.setStyleAttribute(rt1.getElement(), "border", "3px blue solid");
```

Listing 47: Manipulating the widget’s border style with GWT DOM class

Before changing an element’s properties, it is necessary to find them. The next paragraph explains how to find the corresponding element which triggered a browser event. In the example the table cell or row in which the user clicked should be found. Normally this would be the starting point of the editing process, but to keep the example simple the selected cell or row will only be highlighted. Listing A33 and figure A52 show the complete example. The `onPreviewNativeEvent(NativePreviewEvent event)` function is called every time a browser event occurs. The code line `NativeEvent e = event.getNativeEvent()` returns the browser event. Since the web application is only interested in the user’s click down event, the program
filters it out with the following code if("mousedown".equalsIgnoreCase(e.getType()));) Comparing the event against "click" would not be successful, because this handles left clicks but no right ones. The expression Element el = e.getEventTarget().cast() returns the HTML DOM element on which the user clicked. An InlineLabel widget creates a <span> tag. HTML class will become a <div> element and the FlexTable widget produces <table>, <tr> and <td> tags. With this knowledge the test to find out whether the user clicked into a table cell is if("div".equalsIgnoreCase(el.getTagName()));) In this small example, the verification can be done against the HTML tag name. In larger projects it is more secure doing it against an earlier set class name by calling el.getClassName(). The following conditions e.getButton() == NativeEvent.BUTTON_LEFT and e.getButton() == NativeEvent.BUTTON_RIGHT distinguish between a left and a right mouse click on the cell. If the user presses the left mouse button down, the selected cell will be colored yellow by manipulating its background color with the following expression DOM.setStyleAttribute((com.google.gwt.user.client.Element) el, "backgroundColor", "yellow").

Selecting the entire row is slightly more complicated. The information that the <div> tag, which represents the clicked cell, is inside a <td> one and this again is inside the wanted <tr> tag, which represents the row, will be used. Since the <tr> tag has no style attribute, the background color of every cell inside this row has to be changed. Because a row may contain many cells, the <tr> tag may also have a lot of <td> DOM children. A loop iterates over all children, which can be accessed with the following code Element child = (Element) parent.getChild(i), of the <tr> tag. After the <td> cell container has been received, the <div> element can be obtained by executing child.getFirstChildElement(). Finally the background color of the div element will be changed to red.

### 3.5.4 GWT Designer and view optimization using UiBinder

This subsection part shows that the GWT Designer in Eclipse can be used in the same way as the Swing GUI Builder in Netbeans. The GWT Designer is very interesting for new GWT developers, because it displays the text and icon of all available widgets. In order to use the designer, the Java project must be a GWT Designer one\(^{20}\). After a designer Composite class\(^ {21} \) was created, a click at the Java file’s bottom Design tab opens the designer perspective. The view layout can be created by drag and drop. Figure A53 shows creating the login composite panel with the GWT Designer. A right click on the button opens a popup. A ClickHandler can be added by doing a right click on the button and selecting AddEventHandler -> click -> OnClick in the popup menu. The designer generates Java code out of the view and partial vice versa. This means it is possible to add widgets as sequential Java code and the designer will insert them to the view, but creating widgets in loops even with static parameter, e.g. for(int i=0; i<10; i++), will be ignored in the designer version 1.5.

Creating large user interfaces results in a lot of generated and confusing Java code. That is why GWT allows describing user interface with XML. Another advantage of designing views with HTML/XML is that GWT uses the innerHTML attribute to create the views. This means the declarative layout will be converted into an HTML string, which will be inserted into the DOM element’s innerHTML attribute. This technique avoids executing many DOM calls. Page 41 discusses the speed advantage of innerHTML over DOM manipulations by comparing normal (heavyweighted) with cell (lightweighted) widgets.

This passage shows contrasting pairs of normal Java widget code against the corresponding XML one (see listings 48 and 49). The XML code must be inserted into a UiBinder\(^ {22} \) file.

---

\(^{20}\)File -> New -> Project ... -> WindowBuilder -> GWT Designer -> Model -> GWT Java Project

\(^{21}\)File -> New -> Other ... -> WindowBuilder -> GWT Designer -> GWT Java UI -> Composite

\(^{22}\)File -> New -> UiBinder

Michael von Wenckstern: Web Applications Using the Google Web Toolkit
The `g` in `<g:...>` is always defined as `com.google.gwt.user.client.ui`, which is the package of all GWT widgets. Own widgets can only be used, after the complete package namespace has been defined inside the `<ui:UiBinder>` tag. The code line `xmlns:own="urn:import:de.tu_freiberg.informatik.vonwenckstern.client"` represents an example package namespace definition. Afterwards the own components can be used in the following way: `<own:MyComponent>`.</own:MyComponent>.

The comparison of listings 50 and 51 shows the large advantage of XML layout over Java layout. It is important that braces have been set, when passing CSS styles to widgets in the UiBinder. The curly brackets tell the designer to use the above defined style classes and not the class name of the defined styles in the project's CSS files. Listing A34 and figure A54 show a more complex user interface declared in XML.

The attribute `ui:eld` allows access to the widgets in Java files. This is done by adding the `@UiField` annotation before the variable declaration. The name of the variable must be the same as the value of the `ui:eld` attribute. It is important that the visibility of the variable is not private, because otherwise the UiBinder generator has no access to the variable. Listing 52 shows how to handle the click event of the button defined in the XML file.

Creating a declarative layout view with the GWT Designer can be done in the same way as creating Java code. The only difference is that a GWT UiBinder Composite is needed to tell the designer it should describe the view in XML.

3.6 Remote Procedure Calls

3.6.1 Comparison of Remote Procedure Calls with Remote Method Invocations

1981 Birrell and Nelson described the Remote Procedure Call as the following: A process running on machine M1 calls a procedure P on machine M2. M1 is suspended as long as M2 executes P. When M2 returns then M1 continues working. The aim of both people was that

- the call of any remote procedure should be very similar to calling a local function and
- most importantly, neither message passing from M1 to M2 and vice versa nor the variable serialization or any other input/output operations at all should be visible to the programmer.

Most programming languages support Remote Procedure Calls (RPCs) by using a special-purpose Interface Definition Language for describing the interfaces between client and server. Since 1981 the operating systems’ architecture has not supported RPCs, it must be simulated by tools using local procedure calls. This means the tools create a stub component, which the user invokes as a local call. Now, this stub is responsible for all the details (opening, closing the connection, and (de)serialization of parameters), which are necessary for the communication between client and server to work. Figure 21 shows the RPC process. Firstly, the client procedure
calls the local generated client stub function. Secondly, the client stub packs the parameters, creates a message and gives all this to the Communicating Module (CM). Thirdly, the client’s CM sends the received message to the remote computer’s CM. Fourthly, the remote’s CM passes the message to the server stub. Fifthly, the server stub analyses the message and invokes the server procedure with unpacked parameters. Sixthly, the server function does the task and returns the result, an okay or any error notification to the server stub. Seventhly, the server stub packs the result in a message and passes it to the CM. Eighthly, the remote’s CM sends the message to the client’s CM. Ninthly, the client’s CM gives the message to the client stub where the result will be unpacked. Tenthly, the local-invoked client stub function returns the result to the client procedure, and the client procedure can then continue its work. Remote Procedure mechanism handles reference parameters as call-by-values. This means the entire referenced data is copied and transferred to the server. The RPC interface definition is very similar to a set of function declarations in C. It contains the signature of several procedures. The function name and parameter list, which defines the types and notes whether the parameters are input or output ones, belong to the signature.

After the RPC mechanism has been explained, the question arises: How does the client stub know where the server stub is located to exchange the messages. The answer is that the client stub does not know it, unless the remote procedure is registered somewhere. Mapping the service name to a registered server address is called binding. The binding address can be either compiled into all clients or it can be specified at the program start. The program receives the remote procedure location in the following way: The client stub asks the binder service, which address is known, to lookup for the remote procedure name in its table. If the remote procedure name has been registered before, the binding process returns the procedure’s address and the remote call can then start. (These paragraphs are a summary of [Sha].)

Remote Method Invocation (RMI) is the object orientated approach of RPC. This means the object and its method name have to be known to invoke a remote method, instead of only having knowledge of the procedure name in RPC. RMI also supports calls by remote references, where the parameters, which are Remote interfaces, can be passed as arguments. More information on the differences between these technologies can be found at [dif].

Figure A57 and listing 53 shows a Java RMI example, where typed messages can be sent either synchronously or asynchronously to the server. Sending them asynchronously has the advantage that the user interface is not blocked until the response is received. The next passage takes a closure look at the differences between asynchronous RMI calls and synchronous ones. The first difference is that the function, which invokes the synchronous call, returns the result directly and the method, which does an asynchronous call, returns the result via the ActionListener interface. Since the asynchronous version creates a new thread, the client can execute many RMI calls in parallel. Mostly this has advantages, but sometimes it makes handling sequential code more complex. Imagine there is a dropdown list where the user can choose the car brand like BMW. Later the program creates a list, where the user can select the model of the previously picked brand like 3er BMW. Finally, the application creates a list, where the user has to select the correct motorization like BMW 320d. The list can only be created after the user has chosen the model. If all RMI calls are synchronous, then the code could look like the one displayed in listing 54. But if the calls are asynchronous, the code is as complex as shown in listing 55. The last listing shows that the asynchronous model has to use nested ResultListeners to process several steps of data, which depend on RMI results. While it is possible to process synchronous RMI calls in a loop, there is no way to use loops for the asynchronous model. Iterations, which can cause stack overflows, are the substitutes for loops.
3.6.2 GWT’s RPC service and serializable whitelist

The subsection part starts with the confusing statement that GWT’s Remote Procedure Call mechanism is in reality a Remote Method Invocation mechanism without the ability to send an object by remote reference. GWT calls remote methods on objects as shown in a second. GWT only allows making asynchronous RPC calls. In GWT’s RPC service, the website is the client and the web page calls the server, which is always a Java servlet, methods per HTTP POST requests. The easiest way to create a new GWT RPC service is to open GWT RemoteService in Eclipse. Afterwards a client package name like DA_GWTRPC/src/de.tu_freiberg.infor-

---

Listing 53: Exception of RmiClient.java, see listing A35 for complete code

```java
/** wrapper making synchronous RMI asynchronously */
public void getMessage(final String msg, final ActionListener listener) {
    if (listener != null) {
        Runnable run = new Runnable() {
            @Override
            public void run() {
                String result = getMessage(msg);
                listener.actionPerformed(new ActionEvent(this, 0, result));
            }
        };
        Thread t = new Thread(run);
        t.start();
    }
}

/** sending a synchronous RMI message to the server */
public String getMessage(final String msg) {
    try {
        obj = (RmiServer_intf) Naming.lookup("//localhost/RmiServer");
        return obj.getMessage(msg);
    } catch (Exception e) {
        System.err.println("RmiClient exception: "+ e);
        e.printStackTrace();
        return e.getMessage();
    }
}
```

Listing 54: Loading car informations using synchronous RMI calls

```java
CarInfoIntf cars = ...;
JList<String> brands = JList<String>(cars.getBrands());
// ListSelectionEvent handled on brands...
String brand = brands.getSelectedValue();
JList<String> models = JList<String>(cars.getModels(brand));
// ListSelectionEvent handled on models ...
String model = models.getSelectedValue();
JList<String> motors = JList<String>(cars.getMotors(model));
```
Listing 55: Loading car informations using asynchronous RMI calls

Listing 56: Generated CalendarService.java file by Eclipse

- CalendarService.java which is the RPC interface definition.

- CalendarServiceAsync.java is the asynchronous RPC interface. The GWT compiler uses this interface to create a wrapper class to make asynchronous RMI calls. The interface's...
functions can be compared with the public void getMessage(final String msg, final ActionListener listener) method in listing 53 at line 32.

```java
package de.tu.freiberg.informatik.vonwenckstern.client;

public interface CalendarServiceAsync {
}
```

Listing 57: Generated CalendarServiceAsync.java file by Eclipse

- CalendarServiceImpl.java implementing the RPC interface definition.

```java
package de.tu.freiberg.informatik.vonwenckstern.server;
import de.tu.freiberg.informatik.vonwenckstern.client.CalendarService;
import com.google.gwt.user.server.rpc.RemoteServiceServlet;
public class CalendarServiceImpl extends RemoteServiceServlet implements CalendarService {
}
```

Listing 58: Generated CalendarServiceImpl.java file by Eclipse

- Eclipse also registers the Java servlet in the DA_GWTRPC/ war/WEB-INF/ web.xml file by adding the following lines as shown in listing 59.

```xml
<service>
  <servlet-name>CalendarService</servlet-name>
  <servlet-class>de.tu.freiberg.informatik.vonwenckstern.server.
  CalendarServiceImpl</servlet-class>
</service>
<service-mapping>
  <servlet-name>CalendarService</servlet-name>
  <url-pattern>/de.tu.freiberg.informatik.vonwenckstern.GWTRPC/
  CalendarService</url-pattern>
</service-mapping>
```

Listing 59: Modified web.xml file by Eclipse

The CalendarServiceImpl class will be compiled to normal Java byte code. That means the implementation class can use every object of the Java Runtime Environment. Inserting a service interface method ReturnType name(ParameterType1 parameter1, ..., ParameterTypeN parameterN) into the RPC definition file also requires adding the corresponding asynchronous interface method void name(ParameterType1 parameter1, ..., ParameterTypeN parameterN, AsyncCallback<ReturnType> callback) in the asynchronous RPC class. The asynchronous interface uses object classes as return types, e.g. Integer or Void instead of int or void. The calendar service only calls the GregorianCalendar’s get method to collect date information for the website. The interfaces in CalendarService and CalendarServiceAsync are public int get(Date date, int field) and public void get(Date date, int field, AsyncCallback<Integer> callback). After a new interface method has been created, Eclipse generates the asynchronous one by clicking on the error marker left of the synchronous interface definition and choosing generate method get in type CalendarServiceAsync. An easy way to produce the skeletons of the implementation functions is to open the CalendarServiceImpl.java file, click at

Michael von Wenckstern: Web Applications Using the Google Web Toolkit
the error marker next to the class definition and select *add unimplemented methods*, now. This way Eclipse creates a default implementation of the get method. Listing 60 shows the server side implementation of the get function.

```java
30 public int get(Date date, int field) {
31    GregorianCalendar calendar = new GregorianCalendar();
32    calendar.setTime(date);
33    return calendar.get(field);
34 }
```

Listing 60: Implementation of CalendarServiceImpl’s get method

The only thing which has to be done is to invoke the remote get method. Listing 61 displays the `onModuleLoad` function, which calls the server’s get method twice to receive further date information. The `AsyncCallback<T>` interface contains two methods: The first function `public

```java
32 public final static int WEEK_OF_YEAR = 3;
33 public final static int DAY_OF_YEAR = 6;
34 public void onModuleLoad() {
35    CalendarServiceAsync callInfo = CalendarService.Util.getInstance();
36    Date today = new Date();
37    final HTML html = new HTML("Today is: " + today);
38    RootPanel.get().add(html);
39    callInfo.get(today, WEEK_OF_YEAR, new AsyncCallback<Integer>() {
40        @Override
41        public void onSuccess(Integer result) {
42            html.setHTML(html.getHTML() + "<br>We have week number " + result + " now.");
43        }
44        @Override
45        public void onFailure(Throwable caught) {
46            caught.printStackTrace();
47            Window.alert("An error occurred.");
48        }
49    });
60    callInfo.get(today, DAY_OF_YEAR, new AsyncCallback<Integer>() {
61        @Override
62        public void onSuccess(Integer result) {
63            html.setHTML(html.getHTML() + "<br>We have day number " + result + " now.");
64        }
65        @Override
66        public void onFailure(Throwable caught) {
67            caught.printStackTrace();
68            Window.alert("An error occurred.");
69        }
70    });
```

Listing 61: Invoking remote calls to collect more date information

`void onSuccess(T result)` is called when the remote method could be invoked and the server does not throw any exception. `T` is the result type of the `result` variable. It contains the value, which the server implementation returned. The `public void onFailure(Throwable caught)`
function is called, when the server is not reachable, access is denied, or the remote function throws any exception. One important GWT RPC exception is the `StatusCodesException`, which is called when the HTTP status code was not 200 (OK). Table 8 lists the most important status codes.

Table 8: HTTP status codes. Copied from [Fie09]

<table>
<thead>
<tr>
<th>Status Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200 OK</td>
<td>The request has succeeded.</td>
</tr>
<tr>
<td>401 Unauthorized</td>
<td>The request requires user authentication, which is mostly set by a HTTP cookie.</td>
</tr>
<tr>
<td>404 Not Found</td>
<td>The server has not found anything matching the Request-URI. This also happens if the servlet has not been registered in the web.xml file.</td>
</tr>
<tr>
<td>500 Internal Server Error</td>
<td>Response status codes beginning with the digit &quot;5&quot; indicate cases in which the server is aware that it has erred or is incapable of performing the request.</td>
</tr>
</tbody>
</table>

The above example showed that the error handling function of both RPC calls is the same. To avoid writing the same code several times, an abstract `Result` class, which does all the error handling for the application, can be created. Before this class is created, the server side `get` method throws some exceptions. Firstly, the interface method definition has to be changed to `public int get(Date date, int field) throws Exception` in `CalendarService.java`. Secondly, the `get` method in `CalendarServiceImpl.java` will be changed to the one shown in listing 62. Now

```java
public int get(Date date, int field) throws Exception {
    if (date == null)
        throw new NullPointerException("the date object is not allowed to be null");

    if (field < 0)
        throw new IllegalArgumentException("the field argument most be not negative");

    GregorianCalendar calendar = new GregorianCalendar();
    calendar.setTime(date);

    return calendar.get(field);
}
```

Listing 62: CalendarServiceImpl’s `get` method throws exceptions now

the `Result` class will be created as displayed in listing 63. The `AbstractAsyncHandler` class was generated to do general things, which have to be done after every RPC like logging. Another advantage of writing these 'between' class is, that the `Result` class has the same method names as the `AsyncCallback` interface. The remote calls in the `onModuleLoad` function have to be changed as shown in listing 64. The new source code (listing 64) is much more compact than the old one (listing 61). Another advantage is that error handling is not forgotten. This may occur when the application contains hundreds of remote calls and the method implementations of `AsyncCallback` have been created by Eclipse. This example showed that the program does not have to deal with object (de)serialization from the client to the server and vice versa. This is one of the big advantages of the Google Web Toolkit. The compiler analyzes the code and
```java
package de.tu_freiberg.informatik.vonwenckstern.client;
import com.google.gwt.core.client.GWT;
import com.google.gwt.user.client.Window;
import com.google.gwt.user.client.rpc.AsyncCallback;
abstract class AbstractAsyncHandler<T> implements AsyncCallback<T> {
    @Override
    public void onFailure(Throwable caught) {
        GWT.log("RPC Failure [" + this.getClass().getName() + "]", caught);
        handleFailure(caught);
    }
    @Override
    public void onSuccess(T arg) {
        GWT.log("RPC Success [" + this.getClass().getName() + "]", null);
        handleSuccess(arg);
    }
    protected abstract void handleFailure(Throwable caught);
    protected abstract void handleSuccess(T arg);
}

public abstract class Result<T> extends AbstractAsyncHandler<T> {
    @Override
    protected void handleFailure(Throwable caught) {
        onFailure(caught);
    }
    protected void handleSuccess(T arg) {
        onSuccess(arg);
    }
    public void onFailure(final Throwable caught) {
        caught.printStackTrace();
        if (caught instanceof NullPointerException) {
            Window.alert("NullPointer Exception: \n" + caught.getMessage());
        } else if (caught instanceof IllegalArgumentException) {
            Window.alert("IllegalArgumentException: \n" + caught.getMessage());
        }
    }
    public abstract void onSuccess(T arg);
}
```

Listing 63: Source code of Result.java

automatically produces serialization classes for the objects which will be sent over the wire. GWT does not use the powerful standard Java serialization mechanism and this is why not every JRE emulation class can be sent to the server. The following classes are serializable in GWT:

- primitive types such as short, int, byte, and so on; and their object wrappers
- date objects, enumeration classes and strings
- all throwables are serializable
- arrays, ArrayList, HashMap, Stack, Vector and a few more; if these collections and maps only contain serializable types

Michael von Wenckstern: Web Applications Using the Google Web Toolkit
The general java.lang.Object is not serializable. If the Object is a template parameter e.g. in an ArrayList, then the ArrayList is only serializable if the objects are serializable, otherwise the application receives RPC exceptions during runtime. A class is serializable, if all its attributes except final and transient ones are serializable types. As with the normal Java serialization, the class must provide a no parameter constructor. Most times a RPC exception occurs, then a class does not have a default constructor. In order to serialize an ArrayList object containing own defined class types, these class types have to be added to the GWT’s whitelist. The most convenient way is to create a SerializableWhitelist class, which has all class types as attributes. Later, a remote method, which accepts SerializableWhitelist as parameter and as return type, will be created. Listing 65 shows such an example. This example allows one to serialize an ArrayList, which contains a FilePath[] object, but it does not allow one to add a TablePath[] object, because only a TablePath attribute has been added to the SerializableWhitelist class.

GWT also allows defining own (de)serialization methods. [Ker11, p. 80-84] gives more information about this topic.

The end of this subsection shows that it is safer to do the login mechanism with Tomcat instead of creating an own one, which uses GWT RPC calls. The main aim is to illustrate that Google’s RPC mechanism cannot guarantee any security. Listing 66 shows the source code of this example. Manipulating the result is not even difficult: Firstly, a JavaScript debugger will be opened, e.g. pressing F12 in the Internet Explorer. Secondly, the generated script file will be selected and a search for the word "access" will find the location which causes the error message. Thirdly, a breakpoint will be set at this location and the debugging process will start. After
public class LoginServiceImpl extends RemoteServiceServlet
    implements LoginService {
        @Override
        public boolean login(String username) {
            return username.equals("admin") || username.equals("user");
        }
    }

private Button btnLogin = new Button("Login");
private TextBox txtUser = new TextBox();
public void onModuleLoad() {
    VerticalPanel vpanel = new VerticalPanel();
    vpanel.add(new HTML("Insert 'admin' to get administrative rights <br>
        " + "insert 'user' to get only reading rights ");
    vpanel.add(txtUser);
    btnLogin.addClickListener(this);
    vpanel.add(btnLogin);
    RootPanel.get().add(vpanel);
}

@Override
public void onClick(ClickEvent event) {
    LoginService.Util.getInstance().login(txtUser.getValue(), new AsyncCallback<Boolean>() {
        @Override
        public void onSuccess(Boolean result) {
            if (!result) {
                Window.alert("Access denied!");
                return;
            }
            RootPanel.get().clear();
            RootPanel.get().add(new HTML("You are logged in as " + txtUser.getValue()));
        }
        @Override
        public void onFailure(Throwable caught) {
            caught.printStackTrace();
            Window.alert("error occurred");
        }
    });
}

Listing 66: source code showing login mechanism using GWT RPC
Top: server side implementation of RPC, bottom: code for creating the view and calling the server to authenticate the user

tenring any user name into the text box, the web applications calls the server to check the login name. Fifthly, the access variable will be changed from false to true in order to grant access, even if the server denied it. Figure 22 illustrates the hacked results after the debugger’s continue button was pressed. Browser plugins like HackBar for Firefox even allow manipulating POST calls to the server. This way the username can be changed, which grants the attacker more access and allows more damage to be done. For more information about hacking GWT RPC calls see [Gut]. Section 6.5 explains how more secure logins can be done by using Tomcat’s login mechanism and asking for every server operation tomat whether the user has rights to
3.7 History Management

Table 9: GWT application’s URL of different program states

<table>
<thead>
<tr>
<th>State</th>
<th>URL</th>
</tr>
</thead>
<tbody>
<tr>
<td>page1:name=von Wenckstern;firstName=Michael;sex=male;</td>
<td>http://.../survey.html#page1%3Aname%3DvonWenckstern%3BfirstName%3DMichael%3Bsex%3Dmale%3B</td>
</tr>
<tr>
<td>page2:hobbies=soccer,tennis,volleyball;friends=Maren,Stefan,Oliver</td>
<td>http://.../survey.html#page2%3Ahobbies%3Dsoccer%2Ctennis%2Cvolleyball%3Bfriends%3DMaren%2CStefan%2COliver</td>
</tr>
</tbody>
</table>

execute remote calls. This mechanism prevents granting more rights by manipulating POST calls.

The main difference between dynamic and static websites is that dynamic ones will not load a new web page when the user clicks on a hyperlink or triggers any action command. The advantage of dynamic pages is that the browser will not load an entire new website to display new information. This results in a shorter page rendering time, and so the user sees the new information earlier. But dynamic web applications also have a big disadvantage: Because they do not load a new HTML page, the browser does not know that the content has changed. This is the reason why the browser’s history management will not work. The result is that the user cannot navigate to previous application states in most AJAX homepages by pressing the back button. The next example is a web application doing a survey, which contains different questionnaire pages. In this case the user expects to return to the previous page by pressing the browser’s back button. Fortunately, GWT supports manipulating the browser’s history to give the user the expected feeling. GWT allows setting different markers in the URL, which represents different states of web applications. Table 9 shows a mapping of different URLs to different states in the survey example. If the application sets the actual state to the browser history every time the user clicks on the next button, then the browser URL will change. This makes the browser believe
that a new HTML page has been loaded. The browser keeps these URLs which represent the
different web application states. This allows the user to jump to a defined state, which is the
URL part after the pound sign, after the back button has been pressed. Since the URL before the
hash sign did not change, the web browser will not reload the page. The invocation of GWT’s
History.newItem(String state) function sets a new history state to the URL.

The method History.addValueChangeHandler adds a URL changed handler to the rich
internet application. This function receives events when the URL history has been manipulated.
Pressing the forward or backward button in the browser invokes such a notification to the GWT
program.

Figures A55, A56, A58, A59 and listing A36 show an example of how to manipulate the
browser’s history and how to react to history changes caused by the user.

This paragraph explains the most important code parts. Listing 67 illustrates the source code,

```java
129 } else if (title.equals("next1")) {
130     String n = name.getValue().trim();
131     String fn = firstName.getValue().trim();
132     if (n.isEmpty() || fn.isEmpty() || sex.getSelectedIndex() ==
133         -1) {
134         Window.alert("You did not insert all necessary data!";
135     } else {
136         actualState.put("page", "page2");
137         actualState.put("name", n);
138         actualState.put("firstname", fn);
139         actualState.put("sex", sex.getValue(sex.getSelectedIndex()));
140         setHistoryURL();
141     }
142 } else if (title.equals("next2") || title.equals("prev2") { 
```

Listing 67: Source code of Survey.java (excerption, see listing A36 for complete source
code)

which is executed after the user presses the next button on page 1. Line 132 checks if the user
inserted all necessary data. Lines 135 to 139 save the actual state into a HashMap. After this
has been done, the call setHistoryURL in the next line creates a new browser URL out of the
content of the HashMap.

Listing 68 displays the code of this function. Line 177 iterates over all HashMap keys. The

```java
175 public void setHistoryURL() {
176     String state = "";
177     for (String key : actualState.keySet()) {
178         state += key + ":" + actualState.get(key) + ";";
179     }
180     History.newItem(URL.encode(state));
181 }
```

Listing 68: Source code of Survey.java (excerption, see listing A36 for complete source
code)

next line generates a key-value-pair like firstname=Michael. The string state contains all of
the key-value-pairs separated by a semicolon. Line 180 encodes the state to a valid browser
URL, which will be added to the web browser. This causes a notification of the created history
token. That means the `onValueChange` function is invoked straight after the `newItem` method of the History class has been called. If the history changed event should not be fired, then `History.newItem(URL.encode(state), false)` has to be invoked. The second parameter `false` prevents the browser from firing the history changed event. Listing 69 displays the most interesting part of the public void `onValueChange(ValueChangeEvent<String> event)` function.

```java
    String keyValues[] = state.split(";");
    for (String keyValue : keyValues) {
        String key = keyValue.split("=")[0];
        String value = keyValue.split("=")[1];
        actualState.put(key, value);
    }
    RootPanel.get().clear();
    if (actualState.get("page").equals("page1")) {
        firstName.setValue(actualState.get("firstname"));
        name.setValue(actualState.get("name"));
        if (actualState.containsKey("sex")) {
            sex.setSelectedIndex(actualState.get("sex").equals("female") ? 0 : 1);
        } else {
            sex.setSelectedIndex(-1);
        }
        RootPanel.get().add(page1);
    } else if (actualState.get("page").equals("page2")) {
```

Listing 69: Source code of Survey.java (excerption, see listing A36 for complete source code)

Lines 189 to 194 are more or less the opposite of the `setHistoryURL` method shown in listing 68. Line number 195 removes all widgets of the website’s body element. This results in deleting the previously displayed survey page. Lines 197 and 198 set the values of the `TextBoxes` to the ones stored in the `HashMap`. The next line checks whether the `HashMap` contains any information about the user’s sex. This test avoids a null pointer exception when the code `actualState.get("sex").equals(...)` is executed. This check is needed because the user can manipulate the URL directly and so the `sex=male` or `sex=female` parameter can be removed. Line number 204 adds the first survey page to the browser’s body element. This results in showing up the first page with all the information the user inserted earlier. This example demonstrated how any GWT application can support the browser’s forward and back button.

This subsection provides an answer to the question as to how a web application stores its states in GWT. The survey model data has been saved to the URL. This gives the user the opportunity to bookmark the actual website together with the actual data. This way the data is written to the hard disk. The user can share the program state easily by sending anybody the generated URL, e.g. per e-mail. The only limitation is that the URL length is limited 2 MB\(^{26}\). This means that the web program cannot store a gigabyte sized state as a desktop program could do. So the answer whether it is possible to save a web application state in GWT is a partial yes; because small amount of data can be stored and shared, but it does not work for larger data.

---

\(^{26}\) minimum except of IE 10: Firefox 16: 20MB, Chrome 21: 2MB, IE 10: 2 KB; measured with the program shown in listing A37
3.8 Client Bundle

3.8.1 Using ImageResources in the ClientBundle interface

A detailed introduction to ClientBundles can be found at [Goo10e]. This subsection explains how to use image icons in GWT applications with the ClientBundle interface to speed up the application. It also shows how to define browser specific CSS, which are recognized in the GWT deferred binding process.

The speed test program displays 123 push buttons with a specific LaTeX icon. The time needed to show the 123 buttons will be measured with and without the usage of a GWT ClientBundle. The IconsURL class sets the image URL to the push buttons and is displayed in listing 70. The IconsClientBundle class sets the image resource to the push buttons and is shown in listing 71. Line 2 stores the reference containing all images into the im variable.

```java
public class IconsURL extends Grid {

    private final String[] latexIconsURL = new String[] {
        "((a.png",
        "(a.png" . . .
    };

    public IconsURL () {
        ...
        for (String url : latexIconsURL) {
            Image im = new Image("latexImg/" + url);
            PushButton btn = new PushButton(im);
            ...
            this.setWidget(row, col, btn);
        } /* end for */ } /* end IconsURL */ */ /* end class */
}
```

Listing 70: Java code of IconsURL class

```java
public class IconsClientBundle extends Grid {

    private final Images im = Images.Util.getImages () ;

    private final String[] latexIconsClientBundle = new String[] {
        im.img0().getSafeUri().asString(), im.img1().getSafeUri().asString(), ...}

    public IconsClientBundle () {
        ...
        for (String url : latexIconsClientBundle) {
            Image im = new Image(url);
            PushButton btn = new PushButton(im);
            ...
            this.setWidget(row, col, btn);
        } /* end for */ } /* end IconsURL */ */ /* end class */
}
```

Listing 71: Java code of IconsClientBundle class

The next line creates a String array, which contains the link to ImageResources. For any picture smaller than 40 KB, the link of the ImageResource object is equal to the picture’s content. Google uses data URLs to store the content as String. The String value of im.img0().getSafeUri().asString() is "data:image/png;base64,iVBORw0K GgoAAAANSUhEUgAAABUAAAAXCA Y A...". The source code of the Images interface, which extends the ClientBundle interface is shown in listing 72.

Line 2 creates a utility class returning the Images interface. This class is the same for every image client bundle. Line 13 defines the img0 function, which returns the ImageResource of the picture "pics/((a.png". Each method in the Images Interface needs to define the relative path of Michael von Wenckstern: Web Applications Using the Google Web Toolkit
public interface Images extends ClientBundle {
    public static class Util {
        private static Images images = null;
        public static Images getImage() {
            if (images == null) {
                images = GWT.create(Images.class);
            }
            return images;
        }
    }

    @Source("pics/((a.png")
    ImageResource img0();
    @Source("pics/((a.png")
    ImageResource img1();
    ...
}

Listing 72: Java code of Images interface

the image it returns with the Source annotation. In addition to the required Source annotation, the ImageOptions one can be added to define the width, height, or other image options by writing e.g. @ImageOptions(width = 118, height = 156).

In order to inspect the GWT generated classes, which implement the Images interface and return the ImageResources of the pictures, the project has to be compiled with the additional parameter -gen C:\...\DA_ClientBundleImage\gen. Now the files Images_default_InlineClientBundleGenerator.java and Images_default_StaticClientBundleGenerator.java in the directory C:\...\DA_ClientBundleImage\gen\de\tu_freiberg\informatik\vonwenckstern\client\resource can be opened with Eclipse.

The Images_default_InlineClientBundleGenerator class contains private static and final variables externalImage, externalImage0, and so on, which contain the data URL of the images. The declaration of externalImage is private static final java.lang.String externalImage = "data:image/png;base64,iVBORw0K GgoAAAANSUhEUgA..." in these examples. Each function in the Images interface has its own static initializer class, which creates in the constructor the ImageResourcePrototype object with the declared annotation parameter such as width, height, and the data string externalImageX (the @Source parameter). The static get method of this class returns the ImageResourcePrototype object. The implementation of the Images interface’s img0 method returns only the ImageResourcePrototype object of the img0Initializer class. The Images_default_StaticClientBundleGenerator class contains the location of one big picture, which contains all the small images. The static initializer classes extract in their constructor the small image out of the big one. If the web browser supports data URLs, then the GWT compiler will use the Images_default_InlineClientBundleGenerator class as Images interface implementation by default. Adding the code line <set property name="ClientBundle.enableInlining" value="false" / > into the *.gwt.xml file and recompiling the project, forces the compiler to use the Images_default_StaticClientBundleGenerator class to reduce the size of the *.cache.html files.

If the web project sets ClientBundle.enableInlining to false, then the code of the IconsClientBundle needs to be changed as shown in listing 73. The main difference is that the Image object has been created with the ImageResource imRes, instead of creating it with a String containing the link of the ImageResource. If the Image has been created by the ImageResource object, GWT sets the picture as CSS background image. This is needed to cut the desired image.
public class IconsClientBundle extends Grid {

private final Images im = Images.Util.getImages();

private final ImageResource [] latexIconsClientBundle = new ImageResource [] {im.img0(), im.img1() , ...}

public IconsClientBundle() {

...}

for (ImageResource imRes : latexIconsClientBundle) {

    Image im = new Image(imRes);
    PushButton btn = new PushButton(im);
    ...

    this.setWidget(row, col, btn);
} /* end for */} /* end IconsURL() */} /* end class */

Listing 73: Java code of IconsClientBundle class when ClientBundle.enableInlining property is disabled.

out of the big image bundle. If the Image object is created with the code shown in listing 71, then GWT would set the picture as HTML src parameter. The result would be that the large image bundle would be shown every time, instead of the desired small image. The problem with setting a picture as background image is that it can no longer be easily scaled. Changing the size of the Image im object by calling im.setPixel(width, height) will not change the size of the sub picture.

Listing 74 shows the ScalableImage class, which accepts an ImageResource object in the constructor and allows adjusting the size of the sub picture to the wanted pixel size. This code updates the CSS properties background-position, and background-size additional to the CSS properties height and width to achieve the wanted behavior. Listing 75 displays the first three lines in the for each loop. These lines show how to use the ScalableImage to resize the sub images of the large picture bundle. If the ImageResource imRes object has not been added to the root panel, then the onLoad method in the ScalableImage class will not be called, and the image is not shown.

When the browser shows the IconsURL panel, it has to load 123 small pictures from the server. Since the browser only opens a certain number of GET requests at the same time, it needs several GET rounds to load all the images. Figure A60 illustrates the network traffic. The result is that the user has to wait about 3 seconds until all images are loaded. When the user clicks on the "show LaTeX Icons loaded from ClientBundle" button, then all the images are visible immediately. Figure A61 shows the network traffic. The reason is that GWT compiles all the images into the HTML as data URLs, and so the browser does not have to fetch any picture at all. After disabling the ClientBundle.enableInlining property, the browser only loads the big image bundle, which needs about 200ms. Figure A62 displays the network traffic; there were two images loaded, because GWT sets the img src parameter to a transparent one pixel large gif icon. The user does not recognize the 200ms; and because the big picture ends with *.cache.png, it will be downloaded only the first time and the next time it will be loaded from the web browser's cache and is directly available.

Most large web application projects contain several hundred images. There are, for example the standard icons: load, save, print, insert, copy, cut, then there are the arrow and folder icons for any trees like expand, not expand, expand and selected, closed folder, opened folder, closed folder no access, and so on, and there are mostly icons for windows like the close, close-hover, minimize, minimize-hover, maximize, restore, and many border icons with nice color gradients.

\footnote{In this test the compiled GWT project was uploaded to kilo.de, and the page was opened in Firefox at a house with a 6 Mbit/sec download rate.}
import com.google.gwt.resources.client.ImageResource;
import com.google.gwt.user.client.DOM;
import com.google.gwt.user.client.ui.Image;

public class ScalableImage extends Image {
    private int width;
    private int height;
    private ImageResource res;

    public ScalableImage(ImageResource res, int width, int height) {
        this.setUrl(res.getSafeUri());
        this.res = res;
        this.width = width;
        this.height = height;
    }

    @Override
    public void onLoad() {
        int widthOfBigImage = this.getOffsetWidth();
        int heightOfBigImage = this.getOffsetHeight();
        double scaleX = width / res.getWidth();
        double scaleY = height / res.getHeight();
        this.setResource(res);
        DOM.setStyleAttribute(getElement(), "backgroundPosition",
                              Integer.toString((int) (res.getLeft() * -1 * scaleX)) + "px",
                              Integer.toString((int) (res.getTop() * -1 * scaleY)) + "px");
        DOM.setStyleAttribute(getElement(), "backgroundSize", Integer.toString((int) (widthOfBigImage * scaleX)) + "px",
                              Integer.toString((int) (heightOfBigImage * scaleY)) + "px");
        this.setPixelSize((int) (res.getWidth() * scaleX), (int) (res.getHeight() * scaleY));
    }
}

Listing 74: Java code of ScalableImage class allowing to resize the subfigures.

ScalableImage im = new ScalableImage(imRes, 60, 60);
RootPanel.get().add(im); // PushButton class does not fire
onAttach event, so we need to attach the image to the RootPanel
PushButton btn = new PushButton(im);

Listing 75: Example code how to use the ScalableImage class.

Because the user should not have to wait several seconds when it opens a new dialog for the first
time, it is advisable to save the application images into ClientBundles.

3.8.2 Using CssResources in the ClientBundle interface

This subsection part explains the use of ClientBundle’s CssResource types. The example will
be the creation of a CSS transition navigation menu as shown in figure 23. The CSS effect
code is copied from [Chi, pp. 72-73]. First of all, the transitionNavigation.css file has to be

Michael von Wenckstern: Web Applications Using the Google Web Toolkit
created as shown in listing 76. This code contains the special CSS3 transition effects. It will be optimized later. Listing 77 displays the TransitionNavigation interface, which extends the CssResource one. This class has its own interface method for every CSS class definition. There is only one CSS class definition .ownStyle in the CSS file. The name of the interface function can be arbitrary as it will be linked to the CSS class. This is done with the Java annotation @ClassName (without the point).

The navigation.html (see listing 78) file contains the menu’s HTML code. The menu could also be created with the UiBinder interface by writing this HTML code into the XML file, but this example wants to illustrate a different way.

Listing 79 shows the Resources interface extending the ClientBundle one. This interface has the two functions navigation returning the content of the HTML file, and navigationCSS returning the TransitionNavigation interface, which represents the CSS file. The fact that the CSS content will be injected into the browsers DOM before it is used is important. The best way of doing this is to call the ensureInjected function (line 7 in listing 79) directly after the ClientBundle object has been created with GWT.create.

The entry point class CSS is displayed in listing 80. Line 3 stores the Resource interface reference into the variable res. The next line creates an HTML widget with the text specified in navigation.html. Line 6 adds the CSS class ownStyle to the body element in order to override the standard background and text color. That was all the work needed to compile the CSS file into the GWT generated HTML one. The advantage is that the web browser does not have to load the extra transitionNavigation.css file and saves the time for one GET round trip.

The CSS in listing 76 will be optimized and simplified for changes. If the menu entries become larger, then the width properties in li a and ul have to be updated. A person who looks at the CSS code for the first time does not know where it has to change the width. There are two possibilities which make it easier for other persons to enlarge the menu.

- At the top of the CSS file the menuWidth and menuWidthInner parameter can be defined with the following lines:
@charset "ISO-8859-1";

/*
 * CSS copied from Chip magazine Web Design 2013, pp. 72–73
 */

.ownStyle {
  background-color: black;
  color: #6A8916;
}

ul {
  width: 230px;
  background-color: #303728;
  padding: 0px;
}

li {
  list-style-type: none;
}

li a {
  display: block;
  width: 196px;
  padding: 3px 4px;
  margin: 5px 13px;
  color: #969E8D;
  border-bottom: 1px dotted #96BF1F;
  text-decoration: none;
  -moz-transition: background-color 0.3s ease-in;
  -webkit-transition: background-color 0.3s ease-in;
  -o-transition: background-color 0.3s ease-in;
  transition: background-color 0.3s ease-in;
}

li a:hover {
  background-color: #96C11F;
  color: #fff;
  -moz-transition: background-color 0.01s;
  -webkit-transition: background-color 0.01s;
  -o-transition: background-color 0.01s;
  transition: background-color 0.01s;
}

Listing 76: CSS code of transitionNavigation.css file

@def menuWidth 230px;
@def menuWidthInner 196px;

And the width definitions in ul and li a has to be changed as shown in listing 81.

- Alternatively, the outer width will be only defined as a static field in an extra class and two Java functions, which return the menuWidth and the innerMenuWidth calculated out of the width field, will be added. Listing 82 shows an example code. It is important that the menuWidth and innerMenuWidth function return a String, because if the result is e.g. an int value, then the GWT compiler will not evaluate them. The CSS parameters
import com.google.gwt.resources.client.CssResource;

public interface TransitionNavigation extends CssResource {
    @ClassName("ownStyle")
    String ownStyle();
}

Listing 77: Java code of TransitionNavigation interface.

@Resource types:
<ul>
    <li><a href="#ClientBundle">Overview</a></li>
    <li><a href="#DataResource">Data resources</a></li>
    <li><a href="#TextResource">Text and external text resources</a></li>
    <li><a href="#ImageResource">Image resources</a></li>
    <li><a href="#GwtCreateResource">GWT-create resources</a></li>
    <li><a href="#CssResource">CSS resources</a></li>
</ul>

Listing 78: HTML code of navigation.html text file.

public interface Resources extends ClientBundle {
    public static class Util {
        private static Resources res = null;

        public static Resources getResources() {
            if (res == null) {
                res = GWT.create(Resources.class);
                res.navigationCSS().ensureInjected();
            }
            return res;
        }
    }

    @Source("navigation.html")
    TextResource navigation();

    @Source("transitionNavigation.css")
    TransitionNavigation navigationCSS();
}

Listing 79: Java code of Resources interface.

menuWidth and menuWidthInner have to be defined in followed way:
@eval menuWidth TransitionNavigation.Constants.menuWidth();
@eval menuWidthInner TransitionNavigation.Constants.innerMenuWidth();
The ul and li a width definitions are equal to the ones in the first possibility.

I personally prefer the second version better, because only the _menuWidth value has to be changed and the CSS file does not have to be touched at all.

Michael von Wenckstern: Web Applications Using the Google Web Toolkit
public class CSS implements EntryPoint {
    public void onModuleLoad() {
        Resources res = Resources.Util.getResources();
        HTML html = new HTML(res.navigation().getText());
        RootPanel.get().add(html);
        RootPanel.getBodyElement().addClassName(res.navigationCSS().ownStyle());
    }
}

Listing 80: Java code of CSS entry point class.

ul {
    width: menuWidth;
    ...
}
li a {
    width: menuWidthInner;
    ...
}

Listing 81: CSS parameterized with menuWidth and menuWidthInner.

public interface TransitionNavigation extends CssResource {
    public static class Constants {
        /** outer menu width in pixel */
        private static int _menuWidth = 230;
        public static String menuWidth() { return _menuWidth + "px"; }
            // function must return String, otherwise it does not work
        public static String innerMenuWidth() { return Integer.toString(_menuWidth - 34) + "px"; }
    }
    @ClassName("ownStyle")
    String ownStyle();
}

Listing 82: Saving CSS parameter in Java file.

The next paragraphs optimize the CSS code by eliminating unused vendor specific CSS commands like -moz-transition, -webkit-transition, -o-transition and transition. The prefixes -moz-, -webkit- and -o- stand for the vendor specific CSS commands of Mozilla Firefox, Webkit renderer in Safari or Google Chrome, and Opera. Internet Explorer 10 only needs the transition CSS command and will ignore the vendor specific commands anyway, and Chrome only pays attention to the -webkit-transition instruction. This is why conditional CSS should be used to deliver for each web browser only the CSS command it needs and not more. The li a and li a:hover rules in the transitionNavigation.css file are displayed in listing 83.

The available user agent deferred binding values are in gwt-user.jar's com.google.gwt.user-agent.UserAgent.gwt.xml file located and differ from various GWT versions. CSS rules, e.g. for li a, can be defined at different places; the GWT compiler merges them together into one rule. The first occurrence of li a and li a:hover contains the CSS code which is the same for all web browsers; the second one has only the code for the specific browser. In GWT the keywords @if, @elif, or @else define conditional CSS. The condition in @if or @elif always looks like <deferred-binding-property> <space-separated list of values>. Figure A63 illustrates the
compiled result without the usage of conditional CSS, and figures A64, A65, and A66 show it with the usage of conditional CSS. Conditional CSS reduces the size of the *.cache.html files so that they can be downloaded faster.

```css
li a {
  display: block;
  width: menuWidthInner;
  padding: 3px 4px;
  margin: 5px 13px;
  color: #969E8D;
  border-bottom: 1px dotted #96BF1F;
  text-decoration: none;
}
li a:hover {
  background-color: #96C11F;
  color: #fff;
}
@if user.agent gecko1_8 {
  li a { -moz-transition: background-color 0.3s ease-in; }
  li a:hover { -moz-transition: background-color 0.01s; }
}@else
}@endif
```

Listing 83: Using conditional CSS to deliver only browser-specific CSS.

This subsection will finish by showing how the access to ImageResources in CSS files can be established. The above example will be extended with a background picture. Figure 24 illustrates the beautiful final result. The following three lines shown in listing 84 should be added to the Resource interface.

```javascript
@ImageOptions (width=1900) // picture downloaded from
@Source("light_waves.jpg") // http://www.freeimageslive.co.uk/
ImageResource bgImage(); // free_stock_image/lightwavesjpg-0
```

Finally, the CSS class .ownStyle has to be changed as shown in listing 85.

```javascript
@sprite .ownStyle {
  gwt-image: "bgImage";
  color: #6A8916;
}
```

The code `gwt-image: "bgImage"` tells the GWT compiler that it should use the `ImageResource bgImage()` as background picture. In order to use the GWT specific CSS command `gwt-image`, the `@sprite` annotation has to be added before the CSS class definition.

The GWT Client Bundle technology can be compared to the Java mechanism which allows storing resources into the JAR file. If the image resources are small enough, then both store them into one file. In GWT the images are included in the *.cached.html file. The aim of both mechanisms is to speed up the resource loading time by loading them into the browser’s DOM or Random-Access Memory (RAM) before they are actually needed.
4 Model-View-Presenter Architecture

4.1 Comparison of MVP and MVC

This entire subsection is a summary of Interactive Application Architecture Patterns [Der].

Introduction

Both Model-View-Controller and Model-View-Presenter patterns have the goal of separating the concerns of interactive applications: Model-View-Controller (MVC)'s primary design intention was to separate the presentation layer from domain concerns. The existence of the Controller component was a byproduct of dividing the input and output of a program due to the complexities inherited from the host operation system. Today the separation between device input and output at application level has not to be carried out, because most runtime environments like JRE or .NET already do this. This means that the formalize work of the Controller for intercepting user input is no longer necessary in platforms which natively provide this function. Many elemental design patterns as described in Gamma's book "Design Patterns- Elements of Reusable Object-Oriented Software" are well structured patterns giving implementation independent solutions to the most common problems. In order to understand the creation of composite patterns like interaction ones, it is very helpful to understand the history of their further development as no general solution for all platforms exists.

The choice of a design pattern should be made by taking into account the following rule: Firstly a very similar problem, for which a design pattern already exists, should be searched for and then used. However, it is not recommended to use a pattern in which the real life problems were synthetically created after it was first invented.

Model-View-Controller pattern

The MVC pattern was invented to separate the application’s model, presentation and user input into different expert elements. Trygve Reenskaug invented the MVC pattern in 1979 to have an interface for manipulating multiple views of data at once. As the name assumes, the pattern consists of three components: A Model holding the data and business functionality of the program. Generally, real world objects, processes and their behavior will be mapped into a Domain Model. In nearly all applications the View displays the Model data using widgets and other user interface components. The Controller takes care of user input actions like mouse clicks or key hits and thus allows the user to interact with the View and to change the data Model. Figure 25 displays the relationship between these three components.

Every object which can be manipulated by the user, contains of a Model-View-Controller triad. It is important that the Model has neither access to the View nor to the Controller. But both of them can change the Model’s state. The Model can only communicate to the Controller or to the View by sending messages to them. The View and Controller have a link to the Model and work together, allowing the user to manipulate the Model. Since every View is associated with one Controller and vice versa, the Controller class is often a subclass of the View class.
View-Controller represents the presentation layer and the Model the application concerns. The View handles the output, e.g. drawing elements to the screen, and the Controller is responsible for the input, e.g. reacting to user events. This is why both of them have to interact with the Model: The Controller has to manipulate the Model according to the user input. The View has to read the different model data in order to display them.

After the user has triggered some events, the Controller intercepts the input and reacts accordingly. As mentioned before, this can be the interaction with the Model in order to modify some data. Another response can be the change of some visual widgets in the View component, e.g. highlighting scrollbars. In MVC the Controller’s task is not to separate the View from the Model. This division is done by using the Observer Pattern and not the Controller. The Controller was introduced as a link between the end user and the application, and not between the View and the Model.

**MVC pattern for server intensive web applications**

This pattern works very similarly to the previous one, except that the server side input is now processed by specialized components. In JavaServer Pages the MVC separation is done in the following way: HTTP requests are given to the Java Servlet which interacts with the Model and later the Servlet gives the control to a JSP component for generating the HTML code which is then rendered in the browser. The Apache Struts web framework is responsible for the success of this pattern. The aim of the Struts framework was to use the MVC pattern as the following quote shows "The Model represents the business or database code, the View represents the page design code, and the Controller represents the navigational code. The Struts framework is designed to help developers create web applications that utilize MVC architecture." [The08a]

In web applications, a Front Controller administered the common infrastructure concerns (like security, session and login management) and redirects the incoming HTTP requests to individual Controllers. JSP uses a Servlet and ASP.NET an IHttpHandler interface as Front Controller.

In this pattern the Model does the same as in the previous one. The View is the generated HTML content, which can be a rendered text-based template or a compiled object from a template. Similar to the classical MVC pattern is the Controller being responsible for the user input. The only difference is that it does not receive direct hardware signals like mouse down, key pressed, and so on; but it will get this information about the events from the delegated HTTP request. Figure 26 shows how these four components work together.

The Observer Pattern cannot be used to update the View. The Controller generates a class representing all the data and the behavior of the user interface and sends it to the view, which uses this information to generate the HTML code. This means the view only renders the Controller’s output stream.
All Model-View-Presenter (MVP) patterns are a variation of the classical MVC pattern. This subsection introduces two MVP variations: Taligent and Dolphin Smalltalk MVP pattern.

**Taligent Model-View-Presenter pattern**

The Taligent MVP pattern divides the application into data, data manipulation, data specification, user interaction, application coordination, and presentation.

As always, the Model represents the data and business functionality of the program. Selections define parts of the Model’s data on which should be operated, e.g. they can define columns or rows. Commands specify the actions which can be carried out with the data. Similar to the traditional MVC pattern, the View displays the Model data to the user by rendering widgets on the screen. Interactors map user events - like mouse clicks or keyboard input - onto operations which will be executed on the Model. The Presenter creates the proper Models, Commands, Selections, Views and Interactors and manages the interactions between these components. Figure 27 illustrates the relationship of these six components.

The most important differences between this pattern and the classical MVC one are the Presenters and Interactors. The Presenter is like a boss for a particular subsystem within the program. It handles the lifecycle and links between the Model, Views, Commands, Interactors, and Selections. Since Interactors intercept the user events, there is no need for Presenters for every widget. Generally a Presenter exists for each view, but sometimes there are multiple Views for one Presenter. This is the case if there exists separate desktop, tablet and phone views, which are all managed by one Presenter. Interactors can be compared with Controllers in the MVC pattern, because they react to user inputs and call the correct Commands and Selections of the Model.

**Dolphin Smalltalk Model-View-Presenter pattern**

The Dolphin Smalltalk MVP divides the program logic into the three components Model, View and Presenter. By eliminating Selections, Interactors and Commands, the role of the Presenter has been simplified, because now it has only to redirect updates from the View to the Model. The history of the creation of this pattern is quite interesting. Since widgets of the Microsoft Windows operating system already handle most of the controller work, such as user events, the Dolphin Smalltalk team found that the MVC concept of a Controller, whose main task was to react on user events, is no longer needed. This was the reason why they decided to use the Taligent MVP pattern instead of the classical MVC one. But the Dolphin team misinterpreted the
Taligent MVP pattern and so they made the use of an Application Model redundant by inserting the presentation logic from the Model to the Presenter.

As in the MVC pattern, the Model is responsible for the data and business functionality and the View displays the Model data using widgets. The Presenter has the presentation logic interacting with the Model. Figure 28 shows how these components work together.

Now the view manages the user events fired by the operation system and updates it or forwards the events to the Presenter to update the Model. Similar to the Taligent MVP pattern, a single Presenter is responsible for one View most of the time. The Model uses the Observer Pattern to let the View update itself.

**Classical MVC vs. Dolphin Smalltalk MVP**

Because GWT uses the Dolphin Smalltalk MVP pattern and Java Swing the classical MVC one, this paragraph compares these two. Both patterns use a triad-architecture and both of them have a Model and View component with the same functionality. The Controller of the MVC pattern as well as the Presenter of the MVP pattern is used to manipulate the model and the Model uses in both the Observer Patterns to update the View.

In the MVC pattern, the main task of the Controller was to intercept the user inputs. The Controller’s job of changing the Model was only a byproduct which had to be done after receiving the inputs. On the other hand, the Presenter of the MVP pattern was planned to update the Model. In order to change the Model’s data the Presenter has to handle events given by the View.

In GWT it is recommended to use both techniques. The MVP pattern should be used in GWT if the view is a panel which contains many predefined widgets. In this case the View should do the event handling, because all the GWT standard widgets already handle most of the native events and forward these. The View should delegate these events to the Presenter in order to update the Model. The MVC approach should be used in GWT for own created widgets as these have to react to many native events directly, in order to do update its generated HTML. There it is a good idea to let an extra Controller class handle the events.

**4.2 GWT Model-View-Presenter pattern example: Agricola board game**

While the previous subsection gave an introduction about the development history of the Model-View-Presenter pattern, this one explains the pattern on a game example. This subsection shows how to program the Agricola board game in the GWT specific MVP pattern. Google introduced this pattern at the contacts example, which can be found under the title "Large scale application development and MVP" at [Goo10b]. Generally this section follows the Google design, but sometimes it uses different approaches to have more control or to simplify things.

The next paragraphs present the Agricola board game in order to understand the example which will be programmed. The game is a turn-based strategy game, where the player has to build up a farm.
The board contains 14 rounds belonging to six phases of the game. The phases become shorter and shorter the longer the game goes on, the first one consists of four rounds and the last one has only one round. Each phase finishes with a harvest season; where the gamer can crop its fields, has to feed its family, and the animals can re breed. The aim of the game is to be a rich farmer having many different animals, a large family supporting the agrarian, lots of fields to crop grain or vegetables, and to own many acquisitions like pottery, stone stove, or cookery. Before animals can be held, wood has to be collected in order to build a fence. The farmer must plow a field, get seeds, and finally sow its seeds in order to crop grain or vegetables. Before the farmer’s family can have a baby, the house needs to be increased by one room for each new child. Different resources like reed, clay, wood or stone have to be collected to extend the house or to buy new acquisitions. The advantage of such purchases is that they allow the player to do special things like baking bread or killing its animals to make food. The food is needed to feed the family; more family members need more food. I chose this game as MVP example, because:

- It has five playing fields, and so there are at least five views and five presenters.
- The user can interact between these playing fields. This is why an application controller which manages the interaction is needed. The model also requires different events to tell the controller, what happened at one of the playing fields.
- The game is complicated enough to have a model representing the game’s logic and functionality.
- Most of the user inputs can be done by using clicking events.
- The game does not need a server component, and so it can be published at every free web server. This way it can be easily demonstrated to any friends.
- The board game won the "complex board game of the year 2008" award, is very popular and easy to understand. This way it is not difficult to verify whether the program works correctly.

Figure 29 shows a screenshot of the Agricola board game. The package de.tu_freiberg.informatik.vonwenckstern is the root path in the game project hierarchy in Eclipse.
The client package contains:

- Agricola.java,
- AppController.java,
- AppView.java,
- AppView.ui.xml and
- EventBus.java.

The client.event package has the files:

- AddResourceEvent.java,
- BuildFenceEvent.java,
- BuildHouseEvent.java,
- ChildStartsWorkingEvent.java,
- EnableBigAcquisitionEvent.java,
- FamilyAdditionEvent.java,
- FamilyAdditionWithout-HouseEvent.java,
- GetBigAcquisitionEvent.java,
- GetBoarEvent.java,
- GetCowEvent.java,
- GetSheepEvent.java,
- NextRoundEvent.java,
- PlayerFieldDoneEvent.java,
- PlowFieldEvent.java,
- PlowFieldSeedEvent.java,
- ResourceModelChangedEvent.java,
- RestaurateAndFenceEvent.java,
- RestaurateEvent.java,
- SeedEvent.java, and
- ShowingDialogEvent.java.

The client.model package contains the files:

- AcquisitionCardModel.java,
- BackgroundCard.java,
- BaseFieldModel.java,
- BigAcquisitions.java,
- BigFieldModel.java,
- Child.java,
- FieldCard.java,
- HasAcquisitionCardModel.java,
- HasBaseFieldModel.java,
- Player.java,
- PlayerFieldModel.java,
- PlayerResourceModel.java,
- Resource.java, and
- SmallFieldModel.java.

The client.presenter package contains the files:

- BigAcquisitionsPresenter.java,
- CardFieldPresenter.java,
- InfoViewPresenter.java,
- PlayerFieldPresenter.java,
- Presenter.java,
- ResourcePresenter.java,
- Rounds1To7Presenter.java, and
- Rounds8To14Presenter.java.

The client.resources package has the following files:

- Images.java, and
- many jpg and png images.

To the client.view package belong these files:

- AcquisitionCardRenderer.java,
- BigAcquisitionsFieldView.java,
- BigAcquisitionsFieldView.ui.xml,
- BigFieldRenderer.java,
- CardFieldView.java,
- CardFieldView.ui.xml,
- ChildRenderer.java,
- HasPosition.java
- InfoView.java,
- InfoView.ui.xml,
- PlayerFieldView.java,
- PlayerFieldView.ui.xml,
- Renderer.java,
- ResChildRenderer.java,
- ResourceRenderer.java,
- Rounds1To7View.java,
- Rounds1To7View.ui.xml,
- Rounds8To14View.java,
- Rounds8To14View.ui.xml,
- SmallFieldRenderer.java,
- Tooltip.java,
- TooltipImage.java,
- TooltipImageAcquisitionRenderer.java, and
- TooltipImageChildRenderer.java

The project’s package structure above reflects the usage of the Model-View-Presenter pattern. Firstly the model of the game will be explained. The BackgroundCard.java file is an enumeration of the 14 round cards and the five action cards of the game. BigAcquisitions.java file contains the constants for the ten acquisition cards. The Child.java file is a listing of the four col-
ors blue, green, pink, and red of the child stones. The FieldCard.java file is an enumeration of the objects like field, wooden house, and stable, which can be put on the farmyard. The Player.java file is a listing of the four colors a player can choose. The Resource.java file is an enumeration of the possible resources like wood, grain, and boar, which can be collected during the game. The AcquisitionCardModel represents the big acquisition the player bought. The interface HasAcquisitionCardModel is used by view classes having an AcquisitionCardModel. The BaseFieldModel saves the occupation state, the actual number and kind of resources for each round and action card. BigFieldModel extends the BaseFieldModel with the BackgroundCard. HasBaseFieldModel is an interface representing views which have a BaseFieldModel. PlayerResourceModel represents the wooden playing pieces available for the player. SmallFieldModel represents the state of one of the 15 farmyard units. The state stores information such as whether the field is fenced, and if there is a stable; or if the field is a wooden room and how many people are living in it and whether they are at work. PlayerFieldModel represents the player’s property, it contains the acquisitions and all 15 farmyard units. The source code of this model displayed in listing A62 shows that this model contains several functions like getPastureInfo, isPasture, breedAnimals and sendPersonToWork controlling the course of the game. This shows that a model class can contain more than only the getter and setter methods of its field variables, which impression could be created if just a look at the simple GWT contacts tutorial has been taken. This is the advantage of this little bit more complex example.

The resources package contains all the images of the board game and the Images interface, which methods represent the pictures. The usage of such an interface has two advantages: After replacing one picture with another, e.g. if it has a better quality, the source code has only to be changed in this interface class, and there is no need to update all the other classes. The second benefit is that the GWT compiler inlines the images when they are small enough, and this will result in a faster loading time of the web application. Section 3.8.1 explains the usage of ClientBundles. The connection between the interface method name and the image file is done by using the Java Source annotation, e.g. @Source("DSC06140.JPG") ImageResource pottery(). The following code Images::pottery().getSafeUri().asString() returns the picture URL.

AcquisitionCardRenderer, BigFieldRenderer, ChildRenderer, ResourceRenderer and ResChildRenderer extend the GWT widget AbsolutePanel and display the model information of AcquisitionCardModel, BigFieldModel, Child information of BaseFieldModel, selected Resource of BaseFieldModel, and both Child and Resource information graphically. The Tooltip class opens a popup panel with more information about a widget when the user moves its mouse over it. Normally this behavior can be achieved by using the HTML title attribute. But this attribute does not allow line breaks or images. The TooltipImage extends the GWT Image widget by adding user information about this picture in form of the Tooltip class. The most interesting code of this class is shown in listing 86. The Java annotation UiChild allows adding the widget, which contains the additional user information, to the UiBinder. Since every Image can only have one tooltip widget, the limit is set to one. Listing 87 displays how the addTooltip method in any *.ui.xml file can be called. The tooltip widget, which is an HTML widget in this example, can be added by using the UiBinder property tooltip. It is no coincidence

```java
@UiChild(limit=1)
public void addTooltip(Widget tooltip) {
    new Tooltip(this, tooltip);
}
```

Listing 86: UiChild annotation in TooltipImage
Listing A102 shows the complete source code of this class.

Michael von Wenckstern: Web Applications Using the Google Web Toolkit
that the property name is the method name without the add prefix. Both TooltipImageAcquisitionRenderer and TooltipImageChildRenderer extend the TooltipImage class and provide a render method setting the URL of the image depending on the AcquisitionCardModel or BaseFieldModel.

The Rounds8To14.ui.xml file shows, how own widgets like BigFieldRenderer can be used in the UiBinder. Firstly, the client.view package containing the custom widget, has to be imported by adding the attribute xmlns:a='urn:import:de.tu_freiberg.informatik.vonwenckstern.client.view' to the ui:UiBinder tag at the beginning of the xml file. The a stands for Agricola, and every time it is used like <a:?></a:?> in this project, then the widget or the widget’s property as shown in listing 87 belongs to the client.view or client.view.* package. Since the BigFieldRenderer needs a BigFieldModel in order to create an HTML output, it is necessary to create for each BigFieldRenderer widget its own model by writing the code as shown in listing 88. Because the BigFieldModel needs the constants of the enumeration classes Back-

groundCard and Resource, they have to be imported with the following code lines <ui:import field="de.tu_freiberg.informatik.vonwenckstern.client.model.BackgroundCard.*" /> and <ui:import field="de.tu_freiberg.informatik.vonwenckstern.client.model.Resource.*" />. As explained in section 3.5.4, the ui:field attribute is the variable name of the model and has to be unique in the xml file. The code <a:BigFieldRenderer model="{modelBoar}" /> adds the model variable to the widget. This XML code snippet is equivalent to the following line of Java code (new BigFieldRenderer()).setModel(modelBoar). There are two ways of creating an image with the picture defined in the Images interface. In both ways a GWT instance of the Images interface has to be created with the following code line <ui:with field='im' type="de.tu_freiberg.informatik.vonwenckstern.client.resources.Images" />. Either <g:HTML> <img src="{im.rounds8To14.getSafeUri}" /> </g:HTML> or <g:Image url="{im.rounds8To14.getSafeUri.asString}" /> can be used to create the image. The official Google documentation at [Goo02b] uses the resource attribute and not the url one. This means the following line <g:Image resource="{im.rounds8To14}"/> should be used. But
this XML code has one big drawback that it is not easily possible to resize the picture by adding height or width attributes, because the resource version will embed the image as CSS background instead of setting the url attribute. As explained in section 3.8.1 the browser cuts parts away instead of rescaling the entire picture to the required size.

The <g:at left="20" top="35" /> attribute of the AbsolutePanel is the panel position, which is relative of its own one, of the inserted child widget. This technique has been extensively used to put the round cards at the right position above the background images. Figure A67 illustrates the view widgets and their connection to the models. Figure A68 shows the relationship between the views and the presenters in this project. Every view class, which is not just a simple renderer widget, has its own presenter. Every presenter has its own Display interface, which will be implemented by the corresponding view class. The interface is used for the communication between the presenter and its view. This project uses an interface and not a view reference in the presenter to have the opportunity to switch the views without modifying (or with as few as possible modifications in) the presenter class. The project will be extended with a mobile version in the next subsection. This means new mobile views, which implement the same presenter displays as the desktop version, have to be created. In this case there are two views for each presenter. Every presenter class implements the Presenter interface containing a getView function which returns the view widget of the presenter. A comparison of the Presenter interface of this project with the one used in the GWT contacts tutorial shows that the GWT interface has the function go, which takes as parameter a HasWidgets variable. The go version has two disadvantages. The first one is that many panels of older GWT extension libraries like GXT 2.0 do not implement the HasWidgets interface, and so GXT panels cannot be passed as a parameter to the go function. The other disadvantage is that we could not figure work out how to divide the web application into several view parts, where every view has its own presenter and the AppController switches out just one view part and not the entire page, when the go version has been used. One of the following passages about the AppView explains how to switch just one view, when the getView method is used. It may be possible that the go version has advantages in testing the application with JUnit. Apart from the Display interface in InfoViewPresenter, all Display interfaces have at least the two methods asWidget returning the view as widget and the registerHandlers having a ClickHandler object as parameter. The ClickHandler parameter is used to register the click events to the presenter in the view class. These are the only assumptions on the views. This means they consist of widgets, which are able to handle click events as user inputs. Google uses a slightly different way to register several click handlers with its presenter. It prefers the usage of several methods returning the HasClickHandlers interface in their Display interface instead of one registerHandlers method. The disadvantage of this version is that for every button or other widget, which handles click events, one method has to be created. This results in an unnecessary blow up of the Display interface and of the View class. The class code increases, because for every widget, which will be returned in the view implementation of the Display interface method, a UiBinder variable has to be created. And as a result the view class contains many references which may slow down the compiled JavaScript code, just to register events in the presenter class.

The cooperation of presenters and views will be explained at the BigAcquisitionsPresenter and BigAcquisitionsFieldView classes. The presenter class is shown in listing 89. This class defines the Display interface with the two previously mentioned methods and one function with the name hideAcquisition. The constructor needs the view as parameter. After the presenter object has been completely created, the constructor calls in the last line display.registerHandlers(this) method. It tells the view class to register the widget’s click handlers to presenter’s onClick method. The onClick method is called when the user has selected a big acquisition card. This function does nothing other than redirecting the event to the AppController by using the application’s EventBus. More information about the EventBus will be
Listing 89: BigAcquisitions Presenter class

given later. The getView method returns the view as widget by calling the Display’s asWid-
get method. The hideAcquisition function tells the view to dismiss the acquisition card which
the player had bought before. Listing 90 shows the registerHandlers and hidesAcquisition
implementations of the BigAcquisitionsFieldView class.

As displayed in the registerHandlers method, there is no need for any UiBinder variable. The
panel variable has the type AbsolutePanel. The UiBinder binds the panel in view’s con-
structor with the code line panel = binder.createAndBindUi(this). All handlers have been
registered with the given ClickHandler interface by iterating over all panel’s child widgets,
which have the type TooltipImageAcquisitionRenderer. This iteration technique is also used
to hide the image representing the given acquisition. Another advantage of using a loop to reg-
ister the handlers and hide the widget is that the game can be extended more easily with more
acquisitions by simply adding them in the BigAcquisitionsFieldView.ui.xml file; there is no need
to manipulate the BigAcquisitionsFieldView.java file at all. Since the web application has six
presenters BigAcquisitionsPresenter, CardFieldPresenter, InfoViewPresenter, PlayerField-
Presenter, Rounds1To7Presenter, and Rounds8To14 Presenter, they have to send information
to the AppController to share the user inputs with each other. Listing 89 displays the use of the
EventBus to fire events to notify the AppController.

Michael von Wenckstern: Web Applications Using the Google Web Toolkit
4 MODEL-VIEW-PRESENTER ARCHITECTURE

@Override
public void registerHandlers(ClickHandler p) {
    for (int i = 0; i < panel.getWidgetCount(); i++) {
        Widget w = panel.getWidget(i);
        if (w instanceof TooltipImageAcquisitionRenderer) {
            ((TooltipImageAcquisitionRenderer) w).addClickHandler(p);
        }
    }
}

@Override
public void hideAcquisition(BigAcquisitions acquisition) {
    for (int i = 0; i < panel.getWidgetCount(); i++) {
        Widget w = panel.getWidget(i);
        if (w instanceof TooltipImageAcquisitionRenderer &&
            (((TooltipImageAcquisitionRenderer) w).getModel().
                getAcquisition() == acquisition)) {
            w.setVisible(false);
            break;
        }
    }
}

Listing 90: Source code of registerHandlers and hideAcquisition implementations of the BigAcquisitionsFieldView class.

All possible events are located in the package client.event. The java files in this package look very similar. In order to minimize the amount of java files in the client.event package, every file contains the event class, the event handler interface, and the "has event" interface. The idea of having all three classes or interfaces in one file is copied from the GXT 3 library [Sen04]. Listing 91 shows the GetBigAcquisitionEvent.java file.

/** Fires after the user selected a big acquisition */
public class GetBigAcquisitionEvent extends GwtEvent<
        GetBigAcquisitionHandler> {
    /** Handler type */
    private static Type<GetBigAcquisitionHandler> TYPE;

    /** Gets the type associated with this event. */
    @return returns the handler type
    */
    public static Type<GetBigAcquisitionHandler> getType() {
        if (TYPE == null) {
            TYPE = new Type<GetBigAcquisitionHandler>();
        }
        return TYPE;
    }

    private AcquisitionCardModel acquisition;

    public GetBigAcquisitionEvent(AcquisitionCardModel acquisition) {
        this.acquisition = acquisition;
    }

Listing 91: Source code of GetBigAcquisitionEvent.java file.
public AcquisitionCardModel getAcquisition() {
    return acquisition;
}

@SuppressWarnings({"unchecked", "rawtypes"})
public Type<GetBigAcquisitionHandler> getAssociatedType() {
    return (Type) TYPE;
}

@Override
protected void dispatch(GetBigAcquisitionHandler handler) {
    handler.onGetBigAcquisition(this);
}

/** Handler class for {@link GetBigAcquisitionEvent} events. */
public interface GetBigAcquisitionHandler extends EventHandler {
    /** Called when a player selected a big acquisition */
    void onGetBigAcquisition(GetBigAcquisitionEvent event);
}

/** A widget that implements this interface is a public source of
* {@link GetBigAcquisitionEvent} events. */
public interface HasGetBigAcquisitionHandler {
    /** Adds a {@link GetBigAcquisitionHandler} handler for
*   * {@link GetBigAcquisitionEvent} events.
* @param handler the handler
* @return the registration for the event */
    HandlerRegistration addGetBigAcquisitionHandler(
        GetBigAcquisitionHandler handler);
}

Listing 91: GetBigAcquisitionEvent.java file has the three classes GetBigAcquisitionEvent, GetBigAcquisitionHandler, and HasGetBigAcquisitionHandler

The easiest way to create a new event java file is to copy an existing event java file as displayed in listing 91. Then the old event name, e.g. GetBigAcquisitionEvent, has to be replaced with the new event name as well as the old handler name like GetBigAcquisitionHandler with the new handler name. If the replace dialog in Eclipse, which is available after pressing control plus F, is used, then only the two above mentioned replacements have to be carried out. The "has handler" interface name like HasGetBigAcquisitionHandler will be replaced automatically. The handler function name at line 35 and 42 has to be changed to the desired one. Now all the copied boiler plate codes have been changed and the focus will be on the actual event class displayed between lines 17 and 25. In the example the event class has one private variable containing the information, which should be sent from the BigAcquisitionsPresenter class to the AppController one. This data is passed to the event class as constructor parameter and cannot be changed, because the event class has only a getter method of this variable. Listing 92 shows the source code of the EventBus class in the project. Since there is only one EventBus in the project, the singleton pattern can be used. Calling EventBus.getEventBus() gives access to the EventBus. In order to shorten the code when firing events from EventBus.getEventBus().fireEvent( ... )
Listing 92: Source code of EventBus class.

to EventBus.fire( ... ), the static function fire has been added to this class. The EventBus implements all "has handler" interfaces together with the specific handler registration functions. These methods indicate that the EventBus fires the corresponding events. It is important to fire only those events over the EventBus which are needed to communicate between different presenters. If the presenter received an event from its view and can handle it completely alone, then it should not fire this event over the EventBus, as the other presenters are not interested in this event anyway.

The AppView class is only a container view. This gives it the possibility to switch out different parts of the view. The AppView contains an AbsolutePanel having six SimplePanel widgets as children. One of the six views can be simply changed by setting a new widget to one of the SimplePanel objects. The communication between the AppController and the AppView works the same way as the communication between any presenter and its view. Figure A69 shows that the AppController creates and has links to all other presenters. This figure illustrates that the AppController implements many handler interfaces to receive events which must be shared between different presenters. Listing 93 illustrates the onGetBigAcquisition function, which handles the GetBigAcquisitionEvent described above. After the AppController received the event that a user wants to buy a big acquisition, it tests whether this option is allowed. In Agricola, acquisitions can be only bought if one of the family stones is on the buying card. Later the AppController checks whether the player has enough resources to pay for this purchase. If the AppController grants permission to buy the acquisition, it takes the resources from the player, takes this acquisition out of the store, and adds it to the player field. There are three presenters involved in this action (InfoViewPresenter managing the player’s resources, PlayerFieldPresenter adding the new purchase to the player’s farm, and BigAcquisitionsPresenter removing the bought object).

The Agricola class is the application’s starting point. This class just starts the AppController with AppController app = new AppController(new AppView(), Player.BLUE) and attaches the AppView to the root panel with RootPanel.get().add(app.getView()). The start-
Listing 93: Source code of `onGetBigAcquisition` method in the `AppController` class.

As previously mentioned, the advantage of the Model-View-Presenter pattern is that it gives the opportunity to add a new specific view without changing the model, event, and presenter packages. A new mobile view, which does not load the large images and fits perfectly on iPad 2 screens, should be added. Figure 30 shows the new mobile layout of the Agricola board game.
Firstly all java files with exception of HasPosition.java, Tooltip.java, and Renderer.java are copied into the new package client.view.desktop. The client.view.mobile package contains the layout and rendering files specific for the mobile view. Then a new AppViewMobile class has to be created in the client package, which has the general layout of the mobile website. The new structure of the project looks like this:

The client.event, client.model and client.presenter packages are not changed at all. The client package has the files:

- Agricola.java,
- AppController.java,
- AppView.java,
- AppView.ui.xml,
- AppViewMobile.java,
- AppViewMobile.ui.xml, and
- EventBus.java.

The client.view package contains of these following files:

- DesktopViewFactory.java,
- HasPosition.java,
- MobileViewFactory.java,
- Renderer.java,
- Tooltip.java, and
- ViewFactory.java.

To the client.view.desktop package belong these files:

- AcquisitionCardRenderer.java,
- BigAcquisitionsFieldView.java,
- BigAcquisitionsFieldView.ui.xml,
- BigFieldRenderer.java,
- CardFieldView.java,
- CardFieldView.ui.xml,
- ChildRenderer.java,
- InfoView.java,
- InfoView.ui.xml,
- PlayerFieldView.java,
- PlayerFieldView.ui.xml,
- ResChildRenderer.java,
- ResourceRenderer.java,
- Rounds1To7View.java,
- Rounds1To7View.ui.xml,
- Rounds8To14View.java,
- Rounds8To14View.ui.xml,
- SmallFieldRenderer.java,
- TooltipImage.java,
- TooltipImageAcquisitionRenderer.java, and
- TooltipImageChildRenderer.java.

The below listed files belong to the mobile view package client.view.mobile:
AcquisitionCardRenderer.java, BigAcquisitionsFieldView.java, BigAcquisitionsFieldView.ui.xml, BigFieldRenderer.java, CardFieldView.java, CardFieldView.ui.xml, ChildRenderer.java, InfoView.java, InfoView.ui.xml, LabelAcquisitionRenderer.java, PlayerFieldView.java, PlayerFieldView.ui.xml, ResChildRenderer.java, ResourceRenderer.java, Rounds1To7View.java, Rounds1To7View.ui.xml, Rounds8To14View.java, Rounds8To14View.ui.xml, SmallFieldRenderer.java, TooltipPanel.java, and TooltipPanelChildRenderer.java.

The layout of the mobile view is completely different from the layout of the desktop version. As shown in the *.ui.xml files in the view.desktop package nearly all desktop views make use of the AbsolutePanel. However, most *.ui.xml files in the view.mobile package use the Grid object to layout their widgets. The Rounds1To7View.ui.xml mobile file uses the Grid and the VerticalPanel widget to position its renderer widgets. The registerHandlers method of the mobile version of Rounds1To7View.java is displayed in listing 94. In contrast to the desktop

```java
public void registerHandlers(ClickHandler p) {
    for (int r = 0; r < grid.getRowCount(); r++) {
        for (int c = 0; c < grid.getCellCount(r); c++) {
            Widget w = grid.getWidget(r, c);
            if (w instanceof Renderer) {
                w.addDomHandler(p, ClickEvent.getType());
            } else if (w instanceof VerticalPanel) {
                VerticalPanel vp = (VerticalPanel)w;
                vp.getWidget(0).addDomHandler(p, ClickEvent.getType());
                vp.getWidget(1).addDomHandler(p, ClickEvent.getType());
            }
        }
    }
}
```

Listing 94: Source code of registerHandlers method in Rounds1To7View.java file.

version, the view cannot just iterate over the children by using one for loop to register the handlers, it now has to iterate over the rows and columns of the grid. The mobile PlayerField.view.ui file uses VerticalPanels, Grid cells, and HorizontalPanels to create the required layout. In this case the iteration has to be done recursively over the main panel. Listing 95 shows the code of the registerHandlers method. Since this code is universal to register handlers of the wanted widgets of the panel, it will be explained in more detail. The panel variable references to the VerticalPanel having the child widgets Grid, HorizontalPanel, and Grid again. This means that _registerHandlers(..., VerticalPanel) starts with the first Grid widget. Since the Grid widget is a container having more child widgets, the function _registerHandlers(..., Grid1) is invoked again. Grid1 contains many SmallFieldRenderer widgets implementing the Renderer interface. Now the click handler can be added to the SmallFieldRenderer objects. Since Grid1 has no container object as child widget, it will not invoke the _registerHandlers method again. After _registerHandlers(...,Grid1) finished, _registerHandlers(..., VerticalPanel) will continue with VerticalPanel's next child widget: the HorizontalPanel. The function _registerHandlers(...,HorizontalPanel) is called, because HorizontalPanel implements the HasWidgets interface. The child widgets of the HorizontalPanel are one Label and two PushButtons,
Listing 95: Source code of registerHandlers method in PlayerField.java file.

which means no handler is added to them. After _registerHandlers(..., HorizontalPanel) has returned, the last child widget of the VerticalPanel is inspected: the second Grid widget. This means that _registerHandlers(..., VerticalPanel) invokes the function _registerHandlers(..., Grid2), to iterate over the Grid2’s child widgets having the type AcquisitionCardRenderer. Since this type also implements the Renderer interface, the click handler will be added to all Grid2’s child widgets. The operative word is that the mobile views implement the same presenter Display interface as the desktop ones. This gives the opportunity to change the views with each other. This is done by defining a ViewFactory. The code is displayed in listing 96. The interface has methods returning a suitable view for each presenter. The utility class of the

Listing 96: Source code of ViewFactory class.

interface allows access to the presenters’ views at every program place. The following line of code ViewFactory.Util.getViewFactory().getAppView() can be used to access the application’s main view. The GWT.create function, which allows defining specific deferred bindings,
creates the ViewFactory object. One binding replaces this interface with the mobile view implementation of this interface, and the other one uses the desktop view implementation instead of this pure interface. Listing 97 shows a part of the DesktopViewFactory and listing 98 shows fragments of the MobileViewFactory. The only difference between these two listings is that

```java
package de.tu_freiberg.informatik.vonwenckstern.client.view;
import de.tu_freiberg.informatik.vonwenckstern.client.presenter.
        InfoViewPresenter;
import de.tu_freiberg.informatik.vonwenckstern.client.view.desktop.
        InfoView;
... public class DesktopViewFactory implements ViewFactory {
    private static final InfoViewPresenter.Display infoView =
        new InfoView();
    @Override
    public InfoViewPresenter.Display getInfoView() {
        return infoView;
    }
}
```

Listing 97: Source code parts of DesktopViewFactory class.

```java
package de.tu_freiberg.informatik.vonwenckstern.client.view;
import de.tu_freiberg.informatik.vonwenckstern.client.presenter.
        InfoViewPresenter;
import de.tu_freiberg.informatik.vonwenckstern.client.view.mobile.
        InfoView;
... public class MobileViewFactory implements ViewFactory {
    private static final InfoViewPresenter.Display infoView =
        new InfoView();
    @Override
    public InfoViewPresenter.Display getInfoView() {
        return infoView;
    }
}
```

Listing 98: Source code fragments of MobileViewFactory class.

the DesktopViewFactory imports the InfoView class from the view.desktop package and that the MobileViewFactory imports it from the view.mobile package. Please bear in mind that the views should not be created outside the ViewFactory in order to get view deferred binding working properly. This means the presenters in the AppController class have to be created with the code displayed in listing 99.
Finally, the rule defining which ViewFactory should be used has to be added in the Agri-cola.gwt.xml file. Listing 100 shows the code that should be inserted before the </module> tag. Lines 1 to 3 replace the ViewFactory interface with the DesktopViewFactory class. This

```java
ViewFactory vf = ViewFactory.Util.getViewFactory();
leftPresenter = new CardFieldPresenter(vf.getCardFieldView(), player);
middlePresenter = new Rounds1To7Presenter(vf.getRounds1To7View(), player);
infoPresenter = new InfoViewPresenter(vf.getInfoView(), resourceModel);
rightPresenter = new PlayerFieldPresenter(vf.getPlayerFieldView(), playerModel, resourceModel);
bottomPresenter = new Rounds8To14Presenter(vf.getRounds8To14View(), player);
topPresenter = new BigAcquisitionsPresenter(vf.getAcquisitionsView());
```

Listing 99: Source code showing how to create presenters in AppController class.

```java
<replace-with class="de.tu_freiberg.informatik.vonwenckstern.client.view.DesktopViewFactory">
<when-type-is class="de.tu_freiberg.informatik.vonwenckstern.client.view.ViewFactory" />
</replace-with>
<define-property name="ismobile" values="yes,no" />
<property-provider name="ismobile"><![CDATA[
return (navigator.userAgent.indexOf('iPhone') > -1 || navigator.userAgent.indexOf('Android') > -1 || navigator.userAgent.indexOf('iPad') > -1) ? 'yes' : 'no';
]]></property-provider>
<replace-with class="de.tu_freiberg.informatik.vonwenckstern.client.view.MobileViewFactory">
<when-type-is class="de.tu_freiberg.informatik.vonwenckstern.client.view.ViewFactory" />
<when-property-is name="ismobile" value="yes" />
</replace-with>
```

Listing 100: Source code defining the deferred binding for the different ViewFactories.

Smart phone detection code is copied from the book [Dan10] at page 213 means the compiler changes the following line of code private static ViewFactory viewfactory = GWT.create(ViewFactory.class) to private static ViewFactory viewfactory = new DesktopViewFactory(). Line 5 defines the newly deferred binding property ismobile, which can have the two values yes and no. Lines 6 to 11 contain the JavaScript code, which uses the bootstrapper to decide whether it should deliver the desktop or mobile version of the web page. Compiling this GWT application now needs 12 permutations. Section 3.3.2 describes the different permutations and the entire application loading process in more detail.

Michael von Wenckstern: Web Applications Using the Google Web Toolkit
4.4 Introducing activities in the Agricola Model-View-Presenter pattern enabling browser history

At this point, the game is still unable to redo a turn, which has been accidently set. This subsection describes how to implement this new feature. It shows how the MVP application supports history management in such a way that the user can use the browser’s forward and backward button to navigate through the game.

The following Java files will be added to the project hierarchy: In the client package these files will be inserted:

- HistoryController.java, and
- Utils.java.

The following files will be added to the client.event package:

- HistoryChangedEvent.java,
- RequestHistoryEvent.java, and
- SaveHistoryToURLEvent.java.

Normally there is no need to add files to the client.model package. But since firstly some models in the UiBinder xml files were created, they have to be bundled into separate files. The following files should be inserted:

- BigAcquisitationsModel.java,
- CardFieldModel.java,
- HistoryMap.java,
- HistoryMap_CustomFieldSerializer.java,
- Rounds1To7Model.java, and
- Rounds8To14Model.java.

In the client.presenter package only an interface file has been added:

- Activity.java

Not one file has been created in the client.view, client.view.desktop, and client.view.mobile packages.

The Utils.java file contains only a static equals function which checks the equality of objects even if one or both of them are null. The HistoryController class manages the entire history of the application. Since the game needs only one HistoryController, the class uses the singleton pattern. This class has a HistoryMap, which is a normal serializable HashMap with the key and value types Integer and Serializable. The HistoryController uses this map to store the current history state of an Activity class. The Activity interface extends the Presenter interface and has three additional methods:

1. public Type<?> getActivityKey();
2. public T getActualHistory();
3. public void setActualHistory(T state);

In this example the serializable template parameter T represents the model which uses the presenter class to save its state and to restore its view out of a given state. The getActivityKey returns a unique key for every presenter class. The same code is used to generate individual keys as Google does to generate unique keys for their GWTEvent types. In addition to the HistoryMap, the HistoryController has an extra HashMap<Integer, Activity>, the activityPresenterMap, containing all registered Activity presenters, which are interested in changes of their model. The ArrayList<Integer> activityHistoryChanged saves the ids of the presenters, whose state has been changed since the last backup to the browser’s URL. The HistoryController reacts to the following events:

1. The ValueChangeEvent<String> is fired when the browser’s URL has been changed, e.g. when the user presses the back or forward button.
2. The HistoryChangedEvent is fired when the current state of a presenter has been changed.
In this case the activity id of the presenter is added to the activityHistoryChanged ArrayList.

3. The RequestHistoryEvent is fired when a presenter wants to know its current URL state. The presenters fire this event at the end of their constructors to receive the actual state. This event is needed because if the browser opens the web application with the URL address#state, then the GWT History class invokes the ValueChangeEvent<String> directly, with the state token as value. But at this time the AppController is unable to create all of the presenters; and so the presenters need to ask for their actual state in their constructors to show the wanted state information.

4. The SaveHistoryToURLEvent is fired when the HistoryController should save all the states of the registered presenters in the activityHistoryChanged list to the browser's URL. This event will be fired every time after the user has done an entire turn with one person. This means the browser chronic contains the model data of all presenters for each step; and this allows the user to redo and undo all of its playing moves.

Listing 101 has the code of the onHistoryChanged and onRequestHistory functions. These two functions work exactly as described in points two and three in the enumeration above. Listing 102 takes a closer look at the onSaveHistoryToURL method. Lines 4 to 12 actualize the historyMap with the current model states of the activity presenters, which had previously announced their state changes. The changed variable is true, if the new history really differs from the old history one. This check is done as it is possible that the state of a presenter changed twice, so that it does not differ from the last URL backup. Line 16 serializes the historyMap containing the new presenter states to a string. The gwt-versatile serialization library, which is available at [S. ], can be used. Since this library can only be downloaded for GWT 2.4, little changes have to be made in the downloaded source code to make it compatible with GWT 2.5 (The 2.5 version is available on the DVD). Listing 103 shows the beginning of the serialized string of the historyMap. Since this string always starts with the serialization signature of the HistoryMap class, "de.tu_freiberg. . . . .HistoryMap/2831883331" will be removed from the beginning of the serialized string in line 18. The loop in line 19 until 21 replaces the serialization signature of the model classes with shorter names. Lines 22 and 23 abbreviate true with T and false with F. The versatile library uses the \ sign as object separator. The \ sign will be replaced with yy, because

```
@override
def onHistoryChanged(self, event):
    if (!activityHistoryChanged.contains(get_activity().getActivityKey().hashCode())) {
        activityHistoryChanged.add(get_activity().getActivityKey().hashCode());
    }

@override
def onRequestHistory(self, event):
    Serializable s = historyMap.get(event.getActivity().getActivityKey().hashCode());
    event.getActivity().setActualHistory(s);
```

Listing 101: Source code showing the onHistoryChanged and onRequestHistory methods of the HistoryController class.
@Override
public void onSaveHistoryToURL(SaveHistoryToURLEvent event) {
    boolean changed = false;
    for (int historyKey : activityHistoryChanged) {
        Activity a = activityPresenterMap.get(historyKey);
        if (a != null) {
            Serializable oldHistory = historyMap.get(historyKey);
            Serializable history = a.getActualHistory();
            changed |= (oldHistory == null || !oldHistory.equals(history));
            historyMap.put(historyKey, history);
        }
    }
    activityHistoryChanged.clear();
    if (changed) {
        // the history changed
        String serialized = Serializer.serialize(historyMap);
        // removing useless values, because it starts everytime with the same
        serialized = serialized.substring((Serializer
            .getSerializationSignature(HistoryMap.class) + "!!").length());
        for (int i = 0; i < modelNames.length; i++) {
            serialized = serialized.replace(modelNames[i], shortNames[i]);
        }
        serialized = serialized.replace("!!true!!", "!!T!!");
        serialized = serialized.replace("!!false!!", "!!F!!");
        oldHistoryToken = URL.encode(serialized.replace("!!", "yy"));
        History.newItem(oldHistoryToken, false);
    }
}

Listing 104: Shortened and encoded URL string of Listing 103

the model data does not contain two ys in a row and the \ sign must be URL encoded and yy not.
Listing 104 demonstrates the shortened and encoded URL string of listing 103. Listing 105 displays
the most important parts of the onValueChange(ValueChangeEvent<String> event)

Michael von Wenckstern: Web Applications Using the Google Web Toolkit
function. Line 2 gets the actual URL token, which are all characters after the # sign in the

```java
public void onValueChange(ValueChangeEvent<String> event) {
    String token = event.getValue();
    if (token != null && token.equals(oldHistoryToken)) {
        oldHistoryToken = token;
    } else if (token.equals("start")) {
        History.newItem(null, false);
        Window.Location.reload(); // reload the app
    } else { /* 3 */
        String deserialized = URL.decode(token).replaceAll("yy", "\\!");
        // replace other shortcuts to original names
        HistoryMap newHistoryMap = Serializer.deserialize(deserialized);
        for (int key : newHistoryMap.keySet()) {
            if (historyMap.containsKey(key)) { /* 4 */
                Serializable newHistory = newHistoryMap.get(key);
                if (!historyMap.get(key).equals(newHistory)) { /* 6 */
                    /* history of this activity presenter changed */
                    Activity activity = activityPresenterMap.get(key);
                    if (activity != null) { /* 7 */
                        activity.setActualHistory(newHistory);
                    } else if (activityPresenterMap.containsKeyKey(key)) { /* 8 */
                        /* history is new, because the key is not part of historyMap */
                    } else { /* 4 */
                        /* 9 */
                    } /* 10 */
                } /* 5 */
            } /* 4 */
        } /* 3 */
    } /* 2 */
} /* 1 */
```

Listing 105: Source code of onValueChange method of the HistoryController class.

browsers URL. Line 3 checks whether the new token is difference from the actual URL token, because if the new token is the same as the old one then the history does not change. If the new token is equals start, then the entire web application will be reloaded in line 7. Reloading the entire page is done, because it is easier than restoring all the start values. It is important to reset the URL state as shown in line 6 to avoid infinite loop.

Line 9 decodes the URL back to get a normal Unicode string. In line 10 the three ellipses represent the code doing the inverse work to the code displayed in lines 18 to 24 in listing 102. Line 11 deserializes the URL token to the HistoryMap containing the presenters' model data. The loop in lines 12 to 22 iterates over the presenters (the hashmap contains the unique ids of the presenters) and set the models extracted out of the URL to the presenters to let them update their views in line 19.

All of the presenter models have the three methods public void update(T model), public boolean equals(Object o) and public T clone(). Listing 106 gives an example implementation of these functions for the PlayerResourceModel. An update and a clone method has been used to return the model data instead of just returning or changing the model data's reference, because returning the reference will cause the equals method to reply with true for every comparison made in the HistoryController class. If the model's reference has been overwritten instead of using an update function, then all HandlerRegistrations, which have been added to the model to inform the view or presenter after the model data changed, will be lost.

Listing 107 shows the InfoViewPresenter class in place of all other activity presenters (BigAcquisitionsPresenter, CardFieldPresenter, PlayerFieldPresenter, Rounds1To7Presenter, and Rounds8To14Presenter). The presenter registers itself to the model resource change handler to be informed after the model data has changed. Later, the activity presenter adds itself to the HistoryController's activityPresenterMap to get the new model data, which has been extracted out of the URL. In the last line of its constructor, the presenter requests its actual URL model data, which was passed to the web application as loading parameter. The onRe-
sourceChanged method informs the view to update its content and the HistoryController that the model data has changed. As already mentioned above it is important not to return the actual model reference in the getActualHistory function. In the setActualHistory method, the presenter updates its model with the new data entered by the URL and lets the view display the new model data. Another advantage of using the update method instead of assigning the new reference is that the update method can control the model parts which should be changed. This is useful as only the values which may be changed, should be serialized to the URL. The variables, whose value will always be the same, get the transient keyword, which tells the serializer to ignore them. This means these values are not stored into the URL, and so the transient variables have no assigned value after the URL deserialization process. If the reference had been assigned instead of using the update method, then the transient values like the acquisition card descriptions would have been overridden by the no assigned values and this would result in losing data. The advantage of the Model-View-Presenter pattern is that neither any view classes in the client.view, client.view.desktop, and client.view.mobile packages, nor the AppController with its AppView and AppViewMobile classes have to be changed. Now the Agricola board game web application is well structured, making it easier to integrate further extensions. It is also more user-friendly, because it allows the user to change its playing turn by pressing the back button. The complete source code of the Agricola example is available in section A 3.1 and the game can be tested online at [Micc].

Listing 106: Source code of public void update(T model), public boolean equals(Object o) and public T clone() methods of the PlayerResourceModel class.
public class InfoViewPresenter implements Activity<PlayerResourceModel>, ResourceModelChangedHandler {
    public interface Display {
        public void updateView(PlayerResourceModel model);
        public Widget asWidget();
    }

    private Display display = null;
    private PlayerResourceModel model = null;

    public InfoViewPresenter(Display display, PlayerResourceModel model) {
        this.display = display;
        this.model = model;
        model.addResourceModelChangedHandler(this);
        HistoryController.getInstance().addActivityPresenter(this);
        EventBus.fire(new RequestHistoryEvent(this));
    }

    @Override
    public Widget getView() {
        return display.asWidget();
    }

    @Override
    public void onResourceChanged(ResourceModelChangedEvent event) {
        display.updateView(model);
        EventBus.fire(new HistoryChangedEvent(this));
    }

    private static Type<InfoViewPresenter> TYPE = new Type<InfoViewPresenter>("InfoViewPresenter");

    @Override
    public Activity.Type<?> getActivityKey() {
        return TYPE;
    }

    @Override
    public PlayerResourceModel getActualHistory() {
        return model.clone();
    }

    @Override
    public void setActualHistory(PlayerResourceModel state) {
        model.update(state);
        display.updateView(model);
    }
}
5 COMPARISON OF THE TWO WEB FRAMEWORKS: GWT AND JSF

5.1 Definitions of comparison fields

According to point 14 of the Java framework guide from OIO at [Ori02], most Java developers have chosen either JavaServer Faces or Google Web Toolkit in the last two years to create web applications. That is why this section compares these two technologies with each other. As a first step, the comparison fields have to be defined. Both technologies will be tested in the most common website types:

1. Almost completely static sites with a little bit of dynamic content, e.g. news update.
2. Doing a survey in both technologies.
3. Creating a forum to show data.
4. Writing a chat application.
5. Developing a speed game: Snake.

5.2 Comparison in category 1: Nearly completely static sites with a little bit of dynamic content, e.g. news update.

This subsection begins with the first point and with the JSF version. The website has a similar structure to the homepage of the TU Freiberg at http://tu-freiberg.de/. Figure 31 illustrates the layout of the JSF variant. The main.jsf page has a header acting as navigation bar, and on the left side links for special groups. The middle part of the website displays the latest news from the university. The arrows below the news text can be used to navigate to the next or previous message. Majors.jsf has a list of all possible university courses, which can be attended. The list is created dynamically, so that only a new major has to be added into the database and the jsf file...
does not have to be changed. The institutes.jsf page is completely static, because the university will not get a new institute soon.

It is actually really easy to create such a web page with JSF\textsuperscript{28}. At first the managed bean class \texttt{Info}, which contains the functions \texttt{public String[] getMajors()}, \texttt{public int getMaxUniversityNews()}, \texttt{public String decUniversityNews()}, \texttt{public String incUniversityNews()}, and \texttt{public int getUniNewsIndex()}, has to be created. The function \texttt{getMajors} returns a list of all courses which are available at the university. The method \texttt{getMaxUniversityNews} returns the amount of available news to decide whether the actual news is the last one to hide the next button at the web page. The functions \texttt{decUniversityNews}, and \texttt{incUniversityNews} decrement or increment the index counter to show the previous or next piece of news. The \texttt{getUniversityNews} function returns the actual news depending on the index counter. The method \texttt{getUniNewsIndex} returns the news index counter. The complete source code of this class is displayed in listing A124.

The main.xhtml file contains normal static HTML except of the news part, which is shown in listing 108. The code needs the following html namespaces \texttt{xmlns:h=\"http://java.sun.com/jsf/html\"}, and \texttt{xmlns:f=\"http://java.sun.com/jsf/core\"}. Line 2 displays the actual news, the \texttt{escape} attribute has been set to false in order to interpret the value as HTML string and not as text. Since it is not allowed to use \texttt{<} or \texttt{>} letter in an xhtml file, the characters \&lt; for the \texttt{<} sign and \&gt; for the \texttt{>} symbol have to be used as values in the \texttt{commandLink} object. The \texttt{action} attribute in \texttt{commandLink} or \texttt{commandButton} refers to a method which is called after the user has clicked at the link or button. The method has to return a \texttt{String} describing the page to which the user now navigates. For example: if the \texttt{String} is \texttt{"main"}, the user will be redirected to \texttt{"/main.jsf"}. The \texttt{rendered} attribute is true, if the server should draw this object. If it should be hidden, then the value must set to false. In the example, the previous arrows are only visible when the news index is not zero. This means the user cannot navigate to the previous news when the first page is displayed. If the \texttt{commandLink} tags were not included in an \texttt{ajax} tag, the browser would reload the entire website in order to update the news part. This behavior would be inconvenient, because only a small part of the homepage should be updated, without reloading the entire site with many images (the TU Freiberg page has many pictures, this example has only a place holder). The \texttt{render} attribute in \texttt{f:ajax} in line 3 tells the server what part of the page should be updated after the user clicked at any link or button inside the \texttt{f:ajax} tag. In this case the browser DOM element with the id \texttt{uniNews} will be updated. Inside the \texttt{h:panelGroup}
tag, which has the id uniNews, are the components which will be refreshed. In this example
the news text and the arrows should be brought up to date. This example demonstrates that it is
relatively easy to integrate AJAX page updates with JSF.

The JSF code generating a table with all the university courses is displayed in listing 109.

```xml
<panelGrid columns="1">
    <forEach items="#{info.majors}" var="item">
        <outputText value="#{item}" />
    </forEach>
</panelGrid>
```

Listing 109: XML code generating the majors table in the majors.xhtml file.

Complete source code is available in listing A126.

For this code the JSF namespaces xmlns:h="http://java.sun.com/jsf/html", and xmlns:c=
"http://java.sun.com/jsp/jstl/core" is needed. Line 1 creates a table with one column. Line 2
iterates over the string array containing the majors of the college. Lines 3 and 5 are the beginning
and ending of the panelGroup tag defining one table entry. Line 4 writes one string item of the
array into the table entry. JSF makes it very easy to display data from a database.

The next paragraphs implement the same behavior in GWT. Since neither the JSF server has
to be restarted nor any Java classes need to be compiled to add or change any xhtml file, the static
HTML pages cannot be created with the UiBinder or any Java code in GWT as this would result
in recompiling the entire GWT application in order to change the content of any static page. The
GWT application has to request, parse and modify the HTML sites to achieve the same behavior
for static sites in GWT as in JSF. One modification is the change of any internal href string
like `<a href="majors.html">majors</a>` to `<a href="#majors.html">majors</a>`.

Without that modification, the browser would leave the GWT application. The parsing process
looks for any special tags like `[[universityNews]]` or `[[majors]]`, because these tags require
data from the server.

Listing 110 shows the source code of the `onValueChange` function, which loads the HTML
page defined as URL history parameter (it is the string after the # sign in the URL). If the
URL contains no specific parameter, whose side should be loaded, then the URL will be set
to "main.html" in line 4. This is the equivalent to the redirect `<% response.sendRedirect("main.jsf"); %>` in the index.jsp file in the JSF project. Line 6 decodes the URL parameter
to find out which HTML page should be loaded. Line 10 sends a GET request to the server
to receive the content of the HTML website. Line 13 extracts the HTML text from the request
and saves it into the variable `t`. In the next line the hyperlink references will be replaced as
mentioned above. Line 18 checks whether the HTML string contains the special code for the
news widget. If it contains the special code, then it will be replaced with a normal HTML
div tag having a unique id in line 20. The unique id is needed to insert the news widget later.
Lines 23 to 27 parses the HTML code for the majors widget displaying all the courses. Line
28 creates an HTMLPanel with the HTML code `t`, which contains only regular HTML and no
special code anymore. Line 30 inserts the news widget into the HTML panel at the tagged place.
The same replacement will be done with the Majors widget in line 33. The source code for the
UniversityNews (see listing A128) and Majors widgets is a little bit more complex than the JSF
code shown in listing 108 and 109. Listing 111 shows the source code of the Majors widget. The
constructor loads the courses using the GWT RPC mechanism, and the `update` method creates
the HTML table with the loaded content using the GWT Grid widget.

This example has shown that the GWT implementation is much more complex than the JSF
one. The main reason is that a separate parser had to be written and the JSF one could not be
public void onValueChange(final ValueChangeEvent<String> event) {
    String url;
    if (event.getValue() == null || event.getValue().length() == 0) {
        url = "main.html";
    } else {
        url = URL.decode(event.getValue());
    }
    RequestBuilder builder = new RequestBuilder(RequestBuilder.POST, url);
    try {
        builder.sendRequest("GET", url, new RequestCallback() {
            @Override
            public void onResponseReceived(Request request, Response response) {
                String t = response.getText();
                t = replaceHyperlinks(t);
                int id = 0;
                int uniNews = -1;
                int majors = -1;
                if (t.contains("[[ universityNews ]]]")) {
                    uniNews = id;
                    t = t.replace("[[ universityNews ]]]", "<div id="gwt-substitute"+id+""></div>");
                    id++;
                }
                if (t.contains("[[ majors ]]]")) {
                    majors = id;
                    t = t.replace("[[ majors ]]]", "<div id="gwt-substitute"+id+""></div>");
                    id++;
                }
                HTMLPanel f = new HTMLPanel(t);
                if (uniNews > -1) {
                    f.add(new UniversityNews(), "gwt-substitute"+uniNews);
                } else if (majors > -1) {
                    f.add(new Majors(), "gwt-substitute"+majors);
                }
                RootPanel.get().clear();
                RootPanel.get().add(f);
            }
            @Override
            public void onError(Request request, Throwable exception) {
                Window.alert("Failure: Could not load the page: " + URL.decode(event.getValue()) + " from the server.");
            }
        });
    } catch (RequestException e) {
        e.printStackTrace();
    }
}

Listing 110: Java code of onValueChange function in InfoSite.java file.
Complete source code is available in listing A127.
Comparison of the Two Web Frameworks: GWT and JSF

```java
1  public class Majors extends Grid {
2      private String[] majors = null;
3      public Majors() {
4          Infoservice.Util.GetInstance().getMajors(new AsyncCallback<String[]>() {
5              @Override
6              public void onSuccess(String[] result) {
7                  majors = result;
8                  update();
9              }
10              @Override
11              public void onFailure(Throwable caught) {
12                  Window.alert("Could not load majors.");
13              }
14          });
15      }
16  }
17  private void update() {
18      this.resize(majors.length, 1);
19      int i = 0;
20      for (String s : majors) {
21          this.setText(i++, 0, s);
22      }
23  }
```

Listing 111: Java code Majors widget.

used. It would even be possible to parse the JSF xhtml file in GWT so that both technologies can use the same files. It was not done in this example in order to keep the source code as small as possible.

The first category wins JSF clearly with 10:2. GWT gets two points, because it is possible (but with a lot of work) to achieve the same behavior as the JSF application.

5.3 Comparison in category 2: Doing a survey in both technologies.

This subsection generates a survey website in both technologies. Since section 3.7 has already implemented a survey homepage in GWT, only the JSF version will be described here. First of all, listing A129 creates the managed bean class Survey with the following fields: String name, String firstName, boolean male, boolean hobbySoccer, boolean hobbyTennis, boolean hobbyBasketball, boolean hobbyVolleyball, boolean hobbyFootball, boolean hobbyBaseball, ArrayList<SelectItem> friends, String newFriend, and int selectedItem. This class has the following command methods: add, getAllFriends, delete, goToPage1, goToPage2, and goToPage3. Listing 112 shows the add method. The SelectItem represents one item in the list.

```java
1  public String add() {
2      friends.add(new SelectItem(friends.size(), newFriend));
3      newFriend = null;
4      return "page2";
5  }
```

Listing 112: Java code of add method in the Survey.java file.

Michael von Wenckstern: Web Applications Using the Google Web Toolkit
that represents all the friends of the user. The constructor takes two arguments: the first one is the value, which is connected with the item; the second one is the text, which is displayed to the user. The first argument can be any java Object; the last one must be a java String.

The source code of page1.xhtml, page2.xhtml, and page3.xhtml is very easy to understand. Listing 113 displays the body part of the source code of page1. A normal HTML table is used to layout the first survey page. The values of the input elements are automatically loaded from or stored into the managed bean class Survey. This paragraph explains the h:selectOneListBox tag in more detail. A list box has been created which displays two elements at the same time by setting the size attribute to 2. The value of the list box is saved into the boolean variable male. The list box has two selectable items. The first one displays the text "male" to the user and saves the value true into the boolean variable male. The second item illustrates the text "female" and represents the value false to the variable male.

Listing 114 shows the body part of the source code of page2. The user can choose its hobbies by selecting the appropriate checkbox. For example, if the user selects the checkbox with the text soccer, then the boolean variable hobbySoccer has the value true; if the user does not select this checkbox, then variable has the value false. There is a textbox where the user can input the name of its new friend. The friend can be added to the list when the user presses the add button. Listing 112 shows the source code of the add method. All friends are displayed in a list box. Since the list has only a size of ten elements, the user has to scroll if it has more than ten friends. The JSF tag <f:selectItems value="#{survey.friends}"/> says that the ArrayList<SelectItem> friends represents the elements of the list box.

Page3 (listing A130 displays the XML code of page3.xhtml) summarizes the results of the survey. The JSF code <td>Sex: </td><td>#{survey.male ? 'male' : 'female'}</td> displays the sex of the person. The query operator has also been used to list all the user's hobbies by writing <td>Hobbies: </td><td>#{survey.hobbySoccer ? 'soccer, ' : ''} #{survey.hobbyTennis ? 'tennis, ' : ''} ...</td>.

It is very easy to write a survey website in JSF and the developer does not have to bother with history management. Since the survey web page consists of the different pages (page1.jsf, page2.jsf and page3.jsf), the user can navigate through the survey by using the browser's forward and back button. The survey data is available to the user until the browser is closed, because the managed bean class has been annotated with @SessionScoped. Another advantage of using JSF

Michael von Wenckstern: Web Applications Using the Google Web Toolkit
and not the earlier shown GWT version is that the user cannot accidentally pass personal data to a third person by copying the URL and sending it to anybody else. This is because JSF does not save the user data in the URL like GWT.

This means the second category wins JSF with 10:6. GWT receives 6 points, because it is possible to do a survey and there must not be written as much code as in JSF. But in GWT it can happen that the developer forgets the history support and the user has to re-enter all the data when it presses the back button to change any of its earlier inputs. In GWT the user data can also be stored by using the HTML5 `sessionStorage` (for more information see [Refc]). The data is only saved as long as the browser tab is open and the data is not saved into the URL. If this technique is used to support the browser history, then GWT has the same behavior and security as the JSF application.

### 5.4 Comparison in category 3: Creating a forum to show data.

In this subsection JSF runs against GWT in the third category: Writing a forum to show data from a file or a database. In this comparison it does not matter whether the data is loaded from a file or from a database. In both cases the source code is the same, because the server sided part runs in JSF and GWT on Tomcat and the data is returned either by a get function in JSF or by a RPC function in GWT. This means the data reading part is the same in both cases. In order to save the explanation on how to set up a database, the forum data will be loaded from a local file in both cases.

The evaluation starts with the JSF version again. Figure 32 shows the topics.jsf page, which displays the overview of all available topics in the forum and allows the user to create a new
Figure 32: Screenshot of Topic.jsf page.

topic. Figure A70 illustrates the topic entries of "Comments on: You’ll miss me when I’ve
gone" [The]. This page also allows adding a new entry to this topic. The managed bean class
Forum (see listing A131) is request scoped this time and has the two static sub classes:

- Entry representing a forum topic entry. This class has the field variables String
  userName, Date time, and String content. The userName represents the nick name the
  user entered to post its message. The variable time stores the local server time when
  the post was added to the topic and the variable content saves the posted message.
- Topic represents an entire forum topic. It contains the three field variables String
  name, int id, and Entry[] entries. The variable name is the topic name, the variable id
  is needed to access the topic (e.g. when the topic should be loaded then the browser
  opens a URL like: showtopic.jsf?id=1), the array entries contains all the topic entries.

The Forum class has the following field variables String newTopicName, String
userName, String entryText, int topicId, which is connected to the id GET parameter
by using the managed property annotation @ManagedProperty(value="#{param.id}").
The Forum constructor loads the topics array out of the topics.data file by using the
ObjectInputStream. If a new topic is created, or if a user adds a new entry to an
existing topic, then the save method is called, which writes the topics array into the
topics.data file with the ObjectOutputStream. The openNewTopic action method
is displayed in listing 115 and the addNewEntry method is shown in listing 116. Since
line breaks are allowed in the entryText in listings 115 and 116, the HTML key
characters &lt;, &gt;, and & have to be encoded with the following symbols &lt;, &gt;,
and &amp;. If this is not done, the user could enter malicious HTML code, which
would be executed; but this way the HTML code will only be displayed and not executed.

The body part source code of topics.xhtml is shown in listing 117. As explained in
listing 109, an iteration over the topics array will be done with the c:forEach tag. Since
the item.name contains valid HTML code, e.g. hyperlinks, and the hyperlinks should be inter-
parsed as HTML code and not displayed as text source code, the escape attribute has to be set to false. The other JSF tags have already been explained.

The code of showtopic.xhtml (see listing A132) is very similar to the topics.xhtml one: The c:forEach tag iterates over #{forum.topic.entries} to display the topic entries with a h:panelGrid tag, which has the columns attribute 2.

This example showed that it is not difficult at all to create a dynamic forum in JSF. The next passages implement the forum in GWT. The GWT project has three packages: client, shared and server. The client package has the Forum class (see listing A133) and the two RPC interfaces ForumService (see listing A134) and ForumServiceAsync. The shared package has the classes, which are sent from the server to the client or vice versa. These are the Entry class, Topic class, and TopicInformation class. The Entry and Topic classes are similar to the Forum.Entry and Forum.Topic classes in JSF. The TopicInformation (see listing A135) class contains the name of the topic, the id of the topic and the number of topic entries. This class is used to give a topic overview, meaning there is no need to transfer the entire entries array just to count the length, thus saving network traffic and causing the overview page to be loaded faster. The server package contains only the ForumServiceImpl (see listing A136) class implementing the

```
public String openNewTopic() {
    if (newTopicName != null && newTopicName.length() > 0) {
        ArrayList<Topic> topic = new ArrayList<Topic>(Arrays.asList(topics));
        newTopicName = newTopicName.replace(&quot;,&quot;, &quot;&amp;;&quot;).replace(&quot;&lt;&quot;, &quot;&lt;&quot;).replace(&quot;&gt;&quot;, &quot;&gt;&quot;);
        topic.add(new Topic(newTopicName, topic.size(), new Entry[] { }));
        topics = topic.toArray(topics);
        save();
        newTopicName = null;
    }
    return &quot;topics&quot;;
}
```

Listing 115: Java code of the openNewTopic function in the Forum class.

```
public String addNewEntry() {
    if (userName != null && userName.length() > 0 && entryText != null && entryText.length() > 0) {
        ArrayList<Entry> entry = new ArrayList<Entry>(Arrays.asList(topics[topicId].entries));
        entryText = entryText.replace(&quot;,&quot;, &quot;&amp;;&quot;).replace(&quot;&lt;&quot;, &quot;&lt;&quot;).replace(&quot;&gt;&quot;, &quot;&gt;&quot;);
        entry.add(new Entry(userName, new Date(), entryText));
        topics[topicId].entries = entry.toArray(topics[topicId].entries);
        save();
        userName = null;
        entryText = null;
    }
    return &quot;showtopic&quot;;
}
```

Listing 116: Java code of the addNewEntry function in the Forum class.
ForumService interface. The constructor, the save, addNewTopic, and addNewEntry methods of this class are very similar to or the same as in the JSF Forum class.

Listing 118 shows the equivalent Java GWT code of the JSF xhtml code, which is displayed in listing 117. The GWT version has to load the topic information array from the server first. After that the data can be illustrated to the user. This code looks very similar to the code in listing 117, because it also iterates over the array and creates a table to show the data with three columns. The only difference is that a topic has to be loaded with the history parameter like "1" and not with a GET parameter like "?id=1". As the onValueChange method has been used to load the forum topic, the GWT history support has been implemented automatically.

The third category finishes with a tie, because it is very easy in both technologies to write a forum. The reason for this is that the forum is site based, when a new website is loaded for every topic; but the forum is also application based, if the table data of the topic entries table are updated with the new entries of the newly selected topic. GWT is surprisingly good in this category, because the layout of the forum is always the same and so it can be compiled into the static HTML file. This is the main difference between this category and category 1, where the layout of the pages differs a lot (the layout of main.jsf and institutes.jsf was completely different). This is why both technologies earned ten points:

| JSF 10: | ------------ |
| GWT 10: | ------------ |

5.5 Comparison in category 4: Writing a chat application.

Now category 4 will be compared. In this subsection, a web based chat application should be written. Figure 33 shows the screenshot of the chat application. In order to receive the chat answers directly, the long polling technology is used in JSF and in GWT. This means when the chat client is loaded (after the user entered its login name), the browser sends an update request to the server and the server holds this request until any user sends a new message. After the server has received the new message, it returns the update request. Now the web browser has received the update result, which is empty in this case, but the receive event indicates that new
chat messages are available. This means the browser can fetch all the available messages and can send a new update request to be informed when somebody has written a new message.

The JSF version works with IE 10, Chrome 21, and Eclipse Indigo’s integrated web browser; but it does not work in Firefox 16. This will not result in a minus point for JSF, it is probably just a programming error on my part. But nevertheless the example shows how the chat application could work in both technologies.

The comparison starts with the JSF version again. The project has three managed bean classes: Chat (see listing A137) which is application scoped, User (see listing A138) which is session scoped, and Message (see listing A139) which is request scoped. The Chat class is started with the server and is available as long as the server is online, which means that there is only one Chat class for all user requests. This class has a synchronized LinkedList<Message> list field variable storing all the message of the different users, and a synchronized HashMap<Integer, User> users to receive user name and gender from the message list’s userId. The User class has a static integer variable userIds, which allows giving each user a unique userId stored in the integer variable userId. It also contains a string variable nickName, and a boolean variable isMale. The Message class has a string variable message, an integer variable userId, which is connected to the session’s User.userId variable with the managed property @ManagedProperty(value=”#{user.userId}”), and a Date time variable.

This paragraph takes a look at the String send and String getUpdate action methods of the Chat class (see listing 119) to give an understanding of how the long polling technique is implemented. The update request calls the getUpdate function. The code synchronize(this) can be used in this class, because it is known that this class exists only once at

```java
RootPanel.get().clear();
RootPanel.get().add(new HTML("<h1>Forum topics</h1>"));
ForumService.Util.getInstance().getTopics(new AsyncCallback<TopicInformation[]>() {
    @Override
    public void onSuccess(TopicInformation[] s) {
        Grid g = new Grid(s.length, 3);
        for (int i = 0; i < s.length; i++) {
            g.setHTML(i, 0, s[i].getName());
            g.setText(i, 1, s[i].getNumberOfEntries() + "Entries");
            g.setHTML(i, 2, "<a href="#"+ s[i].getId() + ">open topic</a>";
        }
        RootPanel.get().add(g);
        textbox.setValue(null);
        btn.setText("open a new topic");
        HorizontalPanel hp = new HorizontalPanel();
        hp.add(textbox);
        hp.add(btn);
        RootPanel.get().add(hp);
    }
    @Override
    public void onFailure(Throwable arg0) {
        Window.alert("Failure: could not load forum topics");
    }
});
```

Listing 118: Java code excerpt of the onValueChange function in the Forum class.

Michael von Wenckstern: Web Applications Using the Google Web Toolkit
Figure 33: Screenshot of JSF chat application

this server. Then the server calls this.wait() to wait until any user sends a new message in line 20. That was all, the method does nothing else except waiting for new messages. The send method is called when any user sends a new message. Since the Message class is request scoped, the actual request’s message object can be accessed by calling FacesContext.getCurrentInstance().getExternalContext().getRequestMap().get("message"). In the JSF bean notation the first letter of a class, which should always be a capital letter, has to be changed to a small letter. This is why getRequestMethod().get("message") has to be written and not getRequestMap().get("Message"). After the message object has been extracted from the actual request, the addMessage method will be called. This function adds the message to the list and notifies every waiting thread in the getUpdate method that it has received a new message. This causes the threads not to wait anymore, and so the update request returns to the web browser.

The login.xhtml (see listing A140) file contains a <h:inputText value="#{user.nickName}" /> tag where the user can enter its nickname, a <h:selectOneRadio value="#{user.male}" /> tag where the user selects its gender, and a <h:commandButton action="#{chat.login}" value="login" /> tag where the user finishes the login process. Listing 120 shows the source code of the login function in the Chat class. This function uses .getSessionMap().get("user") to get the user object as the User class is session scoped. After the user object is added to the users map, the web browser will be redirected to chatroom.jsf.

Listing 121 demonstrates the JSF code of chatroom.xhtml. Inside <h:outputScript target="head"/> the following JavaScript code is defined: The function f simulates a user click at
public String send() {
    Message msg = (Message) FacesContext.getCurrentInstance().
                    getExternalContext().getRequestMap().get("message");
    addMessage(msg.clone());
    msg.setMessage(null);
    return "chatroom";
}

public void addMessage(Message msg) {
    list.add(msg);
    synchronized (this) {
        this.notifyAll();
    }
}

public String getUpdate() {
    synchronized (this) {
        boolean cont = true;
        while (cont) {
            try {
                this.wait(); // waits until a new message comes in
                cont = false;
            } catch (InterruptedException e) {
                e.printStackTrace();
                cont = true;
            }
        }
    }
    return "chatroom";
}

Listing 119: Java code of the String send and String getUpdate action methods of the Chat class.

public String login() {
    User user = (User) FacesContext.getCurrentInstance().
                  getExternalContext().getSessionMap().get("user");
    addUser(user);
    return "chatroom";
}

Listing 120: Java source code of the login function in the Chat class.

the update button, which results in sending an AJAX update request. This AJAX request calls the getUpdate method of the Chat class. The code window.onload=f means that the function f is invoked after the website is completely loaded. The h:panelGroup tag has the id content and contains the elements which should be updated when the getUpdate request returns. This is the case when any user sends a new message. The <f:ajax render="content" event="change" onevent="f()"> says that the panelGroup should be updated after the update request returned and the event="change" onevent="f()" tells JSF that the function f should be invoked after a successful return of the update event. Normally the <h:commandButton value="send" action="#{chat.send}" /> tag should be inside the f:ajax tag, too. But if so, then nothing happens when the user presses the send button. I wondered why and started the JavaScript de-
bugger. Lines 1324-1329, which is shown in listing 122, in jsf.js display the reason. This means that JSF can, under some circumstances, handle only one AJAX call. But if a new message has been sent to the server using an AJAX call, then there are two active calls in the web browser: The still active update AJAX call, and the newly sent AJAX call. This is the reason why the chat.send call of the send command button is a normal page-reload call and not an AJAX one.

The next passages describe the GWT version of the chat example. There are three packages: client, server, and shared. The client package contains the entry point class Chat (see listing A141) and the two RPC interfaces ChatService (see listing A142) and ChatServiceAsync. The shared package has the classes Message and User. These two classes are very similar to corresponding JSF classes. The server package has only the ChatServiceImpl (see listing A143) class. This class has a static Object lock, which is used in the synchronized block and for the wait and notifyAll methods. This is necessary since nobody knows how many ChatServiceImpl classes Tomcat or Jetty creates.

Listing 123 shows the equivalent GWT source code of listing 121. This code is longer than the xhtml code in the JSF project, but this code is easier to read and write. The sendBtnHandler
is passed as ClickHandler to the send button. This means: If the user presses the send button, then the user message will be sent to the server. After receiving the finished event from the server, which means the new message is added to the list, the current history changed event is fired. This causes the invocation of the onValueChange function, which reloads the chat message table. In onValueChange method the message list will be loaded from the server. After receiving this list, the function loadUsers, which loads the user list from the server, will be called. Both lists are needed in order to map the user ids of the messages to a user name. After receiving both messages a user HashMap will be created and the messages can be rendered into a table. This will be appended to the root panel to show the messages to the user. Later on, the server's update function, which only returns after a new message was added to the list, will be called. This means the onSuccess method of the AsyncCallback cb object is invoked after any user sends a new message. In this onSuccess function, the chat message table will be reloaded and the update function will be invoked again. This way the application updates its messages every time when any user sends a new message. At the start of the program, the application registers the value change handler and calls the onValueChange function by invoking the History.fireCurrentHistoryState method.

In the fourth category, GWT narrowly beats JSF by 10:8. JSF gets 8 points because it does not support multiple AJAX calls under some circumstances. GWT does not win more clearly, because with 203 lines of source code (140 lines Chat.java + 60 ChatService.java + 57 ChatServiceImpl.java) it needs twice the amount of source code as the JSF program with 105 lines (65 Chat.java + 10 login.xhtml + 30 chatroom.xhtml).

<table>

5.6 Comparison in category 5: Writing the speed game Snake.

Finally the classical snake game will be written in both technologies. The aim of the game is to feed the snake so that it grows. In the game, the player has to collect the red pixels which represent the food with its snake. If the snake bites itself or hits the wall, then it will die and the game is over.

This subsection starts with the JSF version. It has one session scoped managed bean class Snake (see listing A144). This class has the fields ArrayList<Point> snakeList, int keyCode, boolean lost, int iContinue, Point food, and Random rand. The snakeList contains the x and y coordinates of the snake body parts. At the beginning the snake has the small size of three body parts and these are located at the points (2,0), (1,0), and (0,0). The first interesting action
1 private final ClickHandler sendBtnHandler = new ClickHandler() {
2 public void onClick(ClickEvent event) {
3     Message m = new Message(ta.getValue(), user.getUserID());
4     ChatService.Util.getInstance().addMessage(m, new AsyncCallback<Void>() {
5         public void onSuccess(Void result) {
6             History.fireCurrentHistoryState(); // reload chat
7         } // onFailure skipped
8     });
9 }
10 }
11 public void onValueChange(ValueChangeEvent<String> event) {
12     ...
13     ChatService.Util.getInstance().getMessages(new AsyncCallback<Message[]>() {
14         public void onSuccess(final Message[] m) {
15             loadUsers(m);
16         } // onFailure skipped
17     });
18 }
19 protected void loadUsers(final Message[] m) {
20     ChatService.Util.getInstance().getUsers(new AsyncCallback<User[]>() {
21         public void onSuccess(User[] u) {
22             HashMap<Integer, User> users = new HashMap<Integer, User>();
23             for (User us: u) {
24                 users.put(us.getUserID(), us);
25             }
26             appendMessages(m, users);
27             AsyncCallback<Void> cb = new AsyncCallback<Void>() {
28                 public void onSuccess(Void result) {
29                     History.fireCurrentHistoryState(); // reload chat
30                 } // onFailure skipped
31             };
32             ChatService.Util.getInstance().update(cb);
33         } // onFailure skipped
34     });
35 }
36 public void onModuleLoad() {
37     History.addValueChangeListener(this);
38     History.fireCurrentHistoryState();
39 }
40
Listing 123: Java code excerption of GWT Chat class.

method is String getImage, which returns the image of the game. Since I did not figure out how to draw an SVG image with JSF, this function creates a 50x50 table and sets the table cells background color to:

- black, when there is a snake body part at this position,
- red, when the food is located at this position, and
- white, when there is no snake and no food.

The other interesting command function String timer moves the snake in the desired direction. The player can control the direction by pressing the arrow keys up, down, left, and right. This function also detects if the snake bites itself or if it can eat the food.
Up to this point the code was pretty straightforward and easy, but the snake.xhtml file contains more JavaScript code than the actual JSF one. Listing 124 displays the source code of snake.xhtml. Since JSF does not allow calling any managed bean function every 100 ms, this code has to be written in JavaScript. In the window.onload function (it is the inline function 1), a timer will be created which calls every 100 ms inline function 2. The inline function 2 checks whether the game is still being played (this means .value == 1) and if so, it simulates a click on the timerButton. This JSF code looks very much like a hack and it would be nice if JSF had a tag which allows to specify the called function and the interval directly; e.g. <f:timer action="#{snake.timer}" interval="100" repeat="true" />. The keydown eventListener has also to be written in JavaScript, because the AjaxBehaviorEvent as parameter in the JSF list-

```xml
<h:head>
  <title>Snake</title>
  <link href="./css/styles.css" rel="stylesheet" type="text/css"/>
  <h:outputScript target="head">
    function () { // inline function 1
      setInterval(function () { // inline function 2
        if (document.getElementById("formId:continue").value == 1) {
          document.getElementById("formId:timerButton").click();
        }
      },100);
    }
  </h:outputScript>
</h:head>

<h:body>
<h:form id="formId">
<h1>Snake</h1>
<h:inputSecret value="#{snake.input}" style="opacity:0.2;"
  position:absolute;left:100px;top:300px;z-index:20;
  width:250px;height:250px" id="keyinput">
</h:inputSecret>
<h:inputHidden id="keyCode" value="#{snake.keyCode}" />
<h:inputHidden id="continue" value="#{snake.iContinue}" />
<h:commandButton value="Restart" action="#{snake.restart}" id="reset">
  <f:ajax render="snakeImage.keyCode" execute="keyCode.continue"/>
</h:commandButton>
<h:outputLabel value="#{snake.image}" escape="false" style=""
  position:absolute;left:100px;top:300px;" id="snakeImage">
</h:outputLabel>
<h:commandButton id="timerButton" action="#{snake.timer}">
  <f:ajax render="snakeImage" execute="keyCode.continue"/>
</h:commandButton>
</h:form></h:body>
```
tener function registered with \(<f:a jax ev en t="k eyup" listener="#\{listener_function\}" />\)
does not contain any information about the JavaScript event. This means the listener\_function is called every time the user presses any key, but there is no way to find out what key the user pressed. This is why the inline function 3 stores the pressed key code into a hidden input field. Since JavaScript only fires key events on elements which have a focus, and the HTML \texttt{table}\ element cannot gain the focus; an \texttt{inputSecret}\ tag, which gets the focus and handles the key events, is used. This \texttt{input}\ element will be put directly over the \texttt{h:outputLabel}\ tag with CSS absolute position and the transparency will be set to 80\% so that it will not hide the snake image completely. The \texttt{h:inputSecret}\ tag and not the \texttt{h:inputText}\ tag has to be used, because if the down arrow is pressed inside the \texttt{h:inputText}\ then the browser suggests the last entered words as popup panel. However the player should not see any popup every time the user wants the snake to go downwards. This JSF code gives the “anything wrong” feeling, because it contains only "hacks". If this code is executed at localhost on the server PC, then it runs fluently. But if it runs on another PC, which is connected with the server over 54 MBit wireless LAN, then the game does not run fluently at all. The game cannot even be played correctly; because if the gamer presses the down key and then the left key the snake does not go down first, it goes directly left and the game is over. The reason for this behavior is that the server is not fast enough in handling the draw event every 100ms. It therefor ignores the fact that the player pressed the down key, and continues right away with the left key.

The GWT implementation needs only the one \texttt{Snake}\ class, which is shown in listing A145. In the \texttt{onModuleLoad}\ function a timer has been created called the \texttt{timer}\ method, which is the same as in the JSF version as has the \texttt{render}\ function, that creates the table output every 100 ms. In GWT the \texttt{onKeyDown}\ function returns the key code of the pressed key. Since this GWT example only needs the server to deliver the HTML file once, then the game runs completely in JavaScript on the local PC, it is fast and does not judder at all.

The last category is won clearly by GWT with 10:0. JSF gets no points, because the game does not even work in the same WLAN, and so it will not work if the player is even further away. In the first category, GWT got 2 points, because it was possible to achieve the same behavior in GWT by writing a renderer and the website could display new static content without recompiling the GWT project. In this category the JSF file had to be extended with a lot of JavaScript code, and even with the additional JavaScript code, the game does not run fluently, and so it is not playable at all.

\begin{tabular}{|l|}
\hline
JSF 0: & 1 \\
GWT 10: & \hline
\end{tabular}

\section{5.7 \textbf{Summary}}

Figure 34 illustrates the points earned by Google Web Toolkit and JavaServer Faces in comparison categories 1 to 5.

JSF has ten points in the categories one to three. All these categories have in common:

- The website displays static or dynamic content to the user.
- The project contains many different static or dynamic web pages.
- The user can navigate through the different websites with the browsers back and/or forward button.
- Web pages use traditional or AJAX based form submissions to send data to the server.
- Most times the web application reacts to click events and not to any other JavaScript events like key pressed, mouse moved, and so on.
GWT won in the categories four and five. These two categories have in common:

- The entire web application has only one web page most of the time.
- The web page has almost no static content; and if it contains dynamic content, then the layout of the dynamic websites is very similar.
- The history management was mostly used to save application data; and not to navigate from one web page to another. If the user navigates with the back or forward button through the web application, then the GWT website will not load a new web page, it only refreshes the content of the same web application.
- The website does not use form based submissions at all to send data to the server. The communication between server and web browser is done by using GWT RPC mechanism, which invokes many asynchronous post calls to the server and calls other JavaScript functions to manipulate the website after receiving the server’s answer.
- All the websites look and behave like traditional desktop application. The web application can easily handle all kinds of JavaScript events like key pressed, mouse moved, focus gained or lost, and so on.

It is not possible to state a clear winning technology, because JSF 2.0 and GWT 2.5 have been developed for different application fields. The technology has to be chosen according to the website’s purpose: JSF if the website is form based and satisfies the characteristics of categories one to three; and GWT if the web page looks and acts like a common desktop application like MS Office.

This means the JSF framework cannot be used as a GWT substitute to create desktop-like web applications.

Michael von Wenckstern: Web Applications Using the Google Web Toolkit
6 Security

6.1 Download Tomcat

Firstly the Tomcat 32-bit or 64-bit Windows zip version has to be downloaded from the official Apache Tomcat page at [Apa]. It is important not to download the Windows Service installer as it is more difficult to configure Eclipse using Tomcat as service. Afterwards the downloaded zip file has to be extracted, e.g. in the eclipse folder to have both Eclipse and Tomcat in the same folder. After which a new server\textsuperscript{32} has to be created in Eclipse with the entries given in table 10. If the configuration has succeeded, then the files shown in figure 35 have been created in the

\begin{table}[h]
\centering
\begin{tabular}{|l|l|}
\hline
Server adapter: & Apache \rightarrow Tomcat v7.0 Server \\
\hline
Server's host name: & localhost \\
\hline
Server runtime environment: & Add \ldots \rightarrow \\
& Name: \rightarrow Apache Tomcat v7.0 \\
& Tomcat installation directory: \rightarrow ..\eclipse\apache-tomcat-7.0.25 \\
& JRE: \rightarrow Workbench default JRE \\
\hline
\end{tabular}
\end{table}

Eclipse Package Explorer. The files context.xml, server.xml, and web.xml will be manipulated later to add user session configuration, database access, and manage the user logins.

6.2 Dynamic Web Application Project with GWT and Tomcat

Firstly, a Dynamic Web Project\textsuperscript{33} has to be created in Eclipse with the entries given in tables 11 and 12.

\begin{table}[h]
\centering
\begin{tabular}{|l|l|}
\hline
Project name: & DA_TomcatGWT \\
\hline
Use default location & checked \\
\hline
Target runtime & Apache Tomcat v7.0 \\
\hline
Configuration & Default Configuration for Apache Tomcat v7.0 \\
\hline
\end{tabular}
\end{table}

\textsuperscript{32}File \rightarrow New \rightarrow Other ... \rightarrow Server \rightarrow Server

\textsuperscript{33}File \rightarrow New \rightarrow Project ... \rightarrow Web \rightarrow Dynamic Web Project
Table 12: Dynamic Web Project wizard part 2.

<table>
<thead>
<tr>
<th>Context root:</th>
<th>DA_TomcatGWT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Content directory:</td>
<td>WebContent</td>
</tr>
<tr>
<td>Generate web.xml deployment descriptor</td>
<td>checked</td>
</tr>
</tbody>
</table>

Secondly, the project has to be converted into a GWT one\(^{34}\). Thirdly, a GWT Module\(^{35}\) has to be added in order to compile the GWT project. The GWT module properties are listed in table 13. Since the GWT project should run on Tomcat and not on Jetty, the Run Configuration\(^{36}\) has to be configured as shown in table 14.

Table 13: GWT module properties.

<table>
<thead>
<tr>
<th>Source folder:</th>
<th>DA_TomcatGWT/src</th>
</tr>
</thead>
<tbody>
<tr>
<td>Module name:</td>
<td>TomcatGWT</td>
</tr>
<tr>
<td>Package name:</td>
<td>de.tu_freiberg.informatik.vonwenckstern</td>
</tr>
<tr>
<td>Create EntryPoint and public resources</td>
<td>checked</td>
</tr>
<tr>
<td>Use MVP framework</td>
<td>not checked</td>
</tr>
<tr>
<td>Configure for third-party toolkit</td>
<td>Use standard GWT only</td>
</tr>
</tbody>
</table>

In order to create the first static files, the project should be compiled before it runs on Tomcat as shown in figure 36.

![Figure 36: Screenshot how to compile the GWT project](image)

If an error occurs, make sure that the GWT SDK library is above the Apache Tomcat library in the build path configuration\(^{37}\) as shown in figure 37.

Before the GWT developer mode can be used, the Tomcat-Server\(^{38}\) has to be started and the entries as shown in table 15 should be selected.

The GWT project should now be run in the development mode\(^{39}\). Because the GWT project has been started for the first time in development mode, the war directory, which is located at \(.../DA_TomcatGWT/WebContent\), has to be selected.

\(^{34}\)right click with mouse on DA_TomcatGWT project folder in Eclipse Project Explorer -> Google Web Toolkit -> Convert project into GWT project ...

</tr>
</tbody>
</table>

| Tab Server: | Embedded Server: Not checked |
| Run build-in server: | |

| Tab GWT: | URL | http://localhost:8080/DA_TomcatGWT/TomcatGWT.html |
| Log level | Info |
| Code Server Port: | 9997 |
| Automatically select an unused port | Not checked |
| Available Modules: | TomcatGWT – de.tu_freiberg.informatik.vonwenckstern |

| Tab Common: | Save as | Local file |
| Display in favorites menu | Debug: checked |
| Launch in background | checked |
| Encoding | Default – inherited (UTF-8) |

Table 15: Wizard showing up when Tomcat is started the first time.

| How do you want to select the server? | Choose an existing server |
| Server | Localhost -> Tomcat v7.0 Server at localhost |
| Always use this server when running this project | checked |
After the Development Mode is started, the URL can be copied by clicking with the right mouse button at the link and selecting the copy menu entry. If this URL has been inserted into the web browser and the page stays blank for a while, then the following steps have to be taken:

1. Open Google Web Application property and select the entries shown in the table below:

| This project has a WAR directory | checked |
| WAR directory | WebContent |
| Launch and deploy from this directory | checked |

2. Terminate the Development Mode by pressing the red square shown in figure 38.
3. Compile the GWT web application again as shown in figure 36.
4. Launch the development mode again.

The client side of the GWT application can be debugged as usually by setting a breakpoint at the required line, e.g. at `clickMeButton = new Button()` in TomcatGWT.java, and launching the development mode in debug mode. Finally, the shown URL should be inserted in the web browser and the debugger stops at the breakpoint. To debug the server side part of the GWT application, Tomcat has to be launched in debug mode.

After opening the Server tab, double clicking at Tomcat v7.0 Server at localhost and changing the Publishing settings as shown in figure 39, the browser website has only to be reloaded after changing any Java code in development mode and there is no need to relaunch the GWT Development mode every time.

6.3 Establish HTTPS connections in Tomcat

6.3.1 Create a pem certificate

First a pem certificate is needed. StartCom [Sta] offers free and verified certificates. If a pem certificate is already available, e.g. the above mentioned one, then this part can be skipped and continue with section part 6.3.2.

This subsection part creates a Hypertext Transfer Protocol Secure (HTTPS) certificate, which is not verified and causes browser warnings. This is done to have a test certificate for this section. Firstly, OpenSSL has to be downloaded at [Ope02]. Secondly, the Visual C++ 2008 Redistributables and afterwards the Win32 OpenSSL v1.0.1eLight have to be installed. If the OpenSSL-Win32\bin folder does not contain an openssl.cnf file, then it has to be downloaded at [Fed] and it has to be saved into the bin directory. Later the cmd.exe should be opened in Windows and the cmd command can be used to go to the OpenSSL-Win32\bin directory folder. Listing 125 shows how to create a 2048 Bit RSA key.

```
$ openssl genrsa -out TomcatGWT.key 2048
```

Listing 125: DOS command to create a 2048 Bit RSA key

Listing 126 displays the command for the signing request. Finally, the certificate can be self-signed with the command illustrated in listing 127.

```
$ openssl x509 -req -days 3650 -in TomcatGWT.csr -signkey TomcatGWT.key -out TomcatGWT.pem
```

Listing 127: DOS command to sign the certificate.
6 SECURITY

<table>
<thead>
<tr>
<th>Line</th>
<th>DOS Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>bin&gt;openssl req -new-key TomcatGWT.key -out TomcatGWT.csr</td>
</tr>
<tr>
<td>2</td>
<td>Loading 'screen' into random state - done</td>
</tr>
<tr>
<td>3</td>
<td>...</td>
</tr>
<tr>
<td>4</td>
<td>If you enter '.', the field will be left blank.</td>
</tr>
<tr>
<td>5</td>
<td>Country Name (2 letter code) [AU]: DE</td>
</tr>
<tr>
<td>6</td>
<td>State or Province Name (full name) [Some-State]: Saxony</td>
</tr>
<tr>
<td>7</td>
<td>Locality Name (eg, city) [ ]: Freiberg</td>
</tr>
<tr>
<td>8</td>
<td>Organization Name (eg, company) [Internet Widgets Pty Ltd]: tu-freiberg</td>
</tr>
<tr>
<td>9</td>
<td>Organizational Unit Name (eg, section) [ ]:</td>
</tr>
<tr>
<td>10</td>

</tr>
<tr>
<td>11</td>
<td>Email Address [ ]: <a href="mailto:unknown@tu-freiberg.de">unknown@tu-freiberg.de</a></td>
</tr>
<tr>
<td>12</td>
<td>...</td>
</tr>
</tbody>
</table>

Listing 126: DOS command to create the signing request

6.3.2 Convert pem certificate into a key store object

Since Tomcat needs a key store object, the certificate has to be converted. Listing 128 shows the first step in how to convert it into a der certificate. The TomcatGWT_cert.der certificate can be opened in the Windows Explorer. Windows warns against the certificate as it is self-signed.

<table>
<thead>
<tr>
<th>Line</th>
<th>DOS Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>openssl pkcs8 -topk8 -nocrypt -in TomcatGWT.key -inform PEM -out TomcatGWT_key.der -outform DER</td>
</tr>
<tr>
<td>2</td>
<td>openssl x509 -in TomcatGWT.pem -inform PEM -out TomcatGWT_cert.der -outform DER</td>
</tr>
</tbody>
</table>

Listing 128: DOS command converting pem certificate.

The program ImportKey should be downloaded from [Ema] and it can be extracted into the OpenSSL bin folder. Listing 129 shows how to execute this program. If the certificate needs a validation chain, then it should be downloaded and renamed to chain.pem. Afterwards the following DOS commands have to be executed: openssl x509 -in chain.pem -inform PEM -out chain.der -outform DER and copy /b TomcatGWT_cert.der+chain.der chain_cert.der.

The chain_cert.der certificate contains the TomcatGWT_cert.der certificate together with its chain certificates. This step is not needed in this example, because there is no certificate chain for the self-signed certificate.

The file keystore.ImportKey should then be copied into the keytool class file location at the JRE installations folder, e.g. \Program Files\Java\jre7\bin. The cmd.exe file should be opened next with administrative rights. After this, the cd command like cd C:\Program Files\Java\jre7\bin should be used to go to the keytool class location. The chain_cert.der certificate (if the certificate needs a certificate chain) can be created with the command shown in listing 130.

Listing 129: DOS command how to execute ImportKey program.
Otherwise the keystore password can be changed with the command displayed in listing 131. The password of the key store will not be replaced here, so it is still importkey. The reason for this decision is to avoid confusion about the key store password.

```
keytool -importcert -alias importkey -file chain_cert.der -keystore keystore.ImportKey
```

Listing 130: DOS command how to import the chain certificate into the key store.

```
keytool -storepassw -keystore keystore.ImportKey
```

Listing 131: DOS command how to change the password of the key store.

### 6.3.3 Configure Tomcat’s XML files to enable HTTPS

The name of keystore.ImportKey has to be changed to TomcatGWT.ImportKey and the file has to be moved into the eclipse folder. The Servers/server.xml file should then be opened in Eclipse, and the `<Connector port ... />` lines has to be changed to the one shown in listing 132. Listing 133 demonstrates the lines, which should be added in the Server/server.xml file. These lines tell Tomcat to redirect any HTTP connection to HTTPS, if HTTPS is supported.

```
<Connector port="8443" protocol="HTTP/1.1" SSLEnabled="true"
ciphers="TLS_RSA_WITH_AES_256_CBC_SHA,TLS_RSA_WITH_AES_128_CBC_SHA"
maxThreads="150" scheme="https" secure="true"
clientAuth="false" sslProtocol="TLS"
keystoreFile="C:\GWT\eclipse\TomcatGWT.ImportKey"
keystorePass="importkey" />
```

Listing 132: XML Connector code in server.xml.

Now the DA_TomcatGWT/WebContent/WEB-INF/web.xml file should be opened and the code displayed in listing 134 can be inserted before the `</web-app>` tag. After that the server has only to be restarted to secure the traffic between any web browser and the server with HTTPS. If a browser opens the website a warning appears, because the self-signed certificate is not valid.

```
<Connector connectionTimeout="20000" port="8080" protocol="HTTP/1.1" redirectPort="8443"/>
```

Listing 133: Enabling HTTP:8080 redirect to HTTPS:8443.

### 6.4 Establish a database connection in Tomcat

#### 6.4.1 Create TomcatGWT user and schema, and add the table countries

If MySQL has not been downloaded, then the MySQL Community Server and the MySQL Workbench from [Orac] must be downloaded and installed. If in MySQL Workbench another server instance exists, then open it, select Users and Privileges, and new user has to be added by pressing the button Add Account and insert the values shown in table 16. After the MySQL Workbench has been opened and a click at the New Connection link in the home screen has been made, the values as shown in table 17 should be inserted.

---

Michael von Wenckstern: Web Applications Using the Google Web Toolkit
Listing 134: Forcing the web application to use only HTTPS connections

```xml
1 <security-constraint>
2   <web-resource-collection>
3     <web-resource-name>Wildcard means whole app requires authentication</web-resource-name>
4     <url-pattern>/</url-pattern>
5   </web-resource-collection>
6   <http-method>GET</http-method>
7   <http-method>POST</http-method>
8   </web-resource-collection>
9   <user-data-constraint>
10     !-- transport-guarantee: CONFIDENTIAL, INTEGRAL, or NONE -->
11     <transport-guarantee>CONFIDENTIAL</transport-guarantee>
12   </user-data-constraint>
13 </security-constraint>
```

Table 16: Wizard Adding new user

<table>
<thead>
<tr>
<th>Tab Login:</th>
<th>TomcatGWT</th>
</tr>
</thead>
<tbody>
<tr>

<td>0</td>
</tr>
<tr>
<td>Concurrent Connections:</td>
<td>0</td>
</tr>
</tbody>
</table>

Figure 40 illustrates how to open the TomcatGWT connection with a double click. The following Structured Query Language (SQL) command `CREATE SCHEMA tomcatgwt` should be inserted into the open SQL File window; afterwards it should be executed.

Since all the administrative rights of the user TomcatGWT were only needed to create the tomcatgwt schema, they should be removed by selecting the TomcatGWT user and pressing the Revoke All Privileges button. Later on, Users and Privileges should be opened again to give TomcatGWT the privileges shown in figure 41. This means the user TomcatGWT can do everything in its own schema and the user has the right to do SELECT queries in the information_schema to find out what tables are available in its own schema.

</tbody>
</table>

Figure 41: Schema Privileges of TomcatGWT user

Figure 40 illustrates how to open the TomcatGWT connection. After clicking with the right mouse button at the tomcatgwt schema, the menu entry Set as Default Schema should be selected. In order to execute queries in the GWT application, a table must be created. The SQL file of all countries in the world can be downloaded from [Gab08]. The countries.sql file can be opened with an arbitrary text editor; the MySQL commands beginning with the CREATE TABLE line and ending with the line (‘Zimbabwe’, ‘zw’, ‘zwe’) can be copied and executed into a new SQL file in the workbench.

6.4.2 Configure Tomcat’s XML files to get access to the database connection

The MySQL database connector can be downloaded from [Orad]. The JAR file mysqlconnector-java-5.1.18-bin.jar can be copied into the folder ...apache-tomcat-7.0.25\lib.
After the Servers/server.xml file has been opened, the lines displayed in listing 135 should be inserted below `<GlobalNamingResources>`.

Listing 136 shows the code, which has to be inserted into Servers/context.xml file after the line `<Context>`.

To test the database connection, a simple RPC call, which delivers all the country names in the database, will be created. The remote CountryService interface has the one method String[] getCountries(). At the beginning of the onModuleLoad function in the TomcatGWT.java file, the lines displayed in listing 137 can be added.

Listing 138 displays the getConnection function in the CountryServiceImpl remote class. This code returns one MySQL connection from the connection pool, which has been added in listing 135 to Tomcat. The getCountries function implementation is displayed in listing 139.

The TomcatGWT program can now be executed. If the RPC call fails, then the project must be recompiled to add the new getCountries remote function to the GWT whitelist. Figure 42 shows a screenshot of the remote database result.

    name="jdbc/TomcatGWT"
    global="jdbc/global_TomcatGWT"
/>
```
Listing 137: Java code requesting all countries in the database in the `onModuleLoad` function

```java
public void onSuccess(String[] countries) {
    String alertStr = " ";
    for (String country : countries) {
        alertStr += \n" + country;
    }
    Window.alert(alertStr);
}
```

Listing 138: Java code of `getConnection` function

```java
public static Connection getConnection() throws Exception {
    String jdbcname = \"jdbc/TomcatGWT\";
    Context ctx = new InitialContext();
    Context envCtx = (Context) ctx.lookup(\"java:comp/env\");
    DataSource ds = (DataSource) envCtx.lookup(jdbcname);
    Connection conn = ds.getConnection();
    return conn;
}
```

Listing 139: Java code of `get Countries` remote implementation.

```java
public String[] get Countries() {
    ArrayList<String> list = new ArrayList<String>();
    try {
        Connection con = null;
        con = getConnection();
        PreparedStatement ps =
            con.prepareStatement("SELECT name, alpha_2 from countries ");
        ResultSet rs = ps.executeQuery();
        while (rs.next()) {
            list.add(rs.getString(1) + \"(" + rs.getString(2) + \")\")
        }
    } catch (Exception e) { e.printStackTrace();}
    finally {
        if (con != null) {
            try { con.close(); } catch (SQLException e) { e.printStackTrace(); }
        }
    }
    String[] s = new String[list.size()];
    list.toArray(s);
    return s;
}
```
6.4.3 PreparedStatements avoid MySQL injections

This paragraph describes how the user can add a new country into the database. One time the country is added with the unsafe method `con.createStatement().executeUpdate()`, and the second time it is inserted into the table with the safe function `con.prepareStatement()`.

The two functions have to be added to the `CountryService` remote interface: `void insertCountryUnsafe(String name, String shortName1, String shortName2)` and `void insertCountrySafe(String name, String shortName1, String shortName2)`. Listing 140 shows the code of the string connected MySQL Statement. Listing 141 displays the equivalent of listing 140 with the usage of `PreparedStatement`. If the user enters in the name field only a text containing no special characters (e.g. my own country), then the behavior is the same in both

```
1 public void insertCountryUnsafe(String name, String shortName1,
2     String shortName2) {
3     ...  
4     String query = "INSERT INTO 'countries' ('name', 'alpha_2', 'alpha_3')
5         VALUES (" + name + ", " + shortName1 + ", " + shortName2 + ");
6     con.createStatement().executeUpdate(query);
7     ...
8 }
```

Listing 140: Java code of unsafe function.
functions. But if the text contains any special character like ' (e.g. if the user enters Michael’s own country), then the insertCountyUnsafe method will fail, because the String query contains no valid SQL anymore.

In the unsafe method, the user can even inject malicious MySQL, e.g. when the user inputs the code shown in table 18.

Table 18: Example how to inject MySQL code into the unsafe function.
Later on 1 can be replaced with 3, 5, 7, and 9, and 4 can be changed to 1, 2, 3, and so on.

| Name: | `. (SUBSTRING((select ‘User’ from mysql.user LIMIT 4,1),1,2)),/*` |
| Short name 1: | (empty) |
| Short name 2: | `*/` |

Figure 43: MySQL injection shows secret database login.

Figure 44: Safe function prevents MySQL injections.

Figure 43 illustrates a screenshot of how the hacker finds out the secret database login "TomcatGWT". If the ‘User’ string is changed to ‘Password’ in table 13, then the hacker knows the hash sum of the password. The attacker now has the administrative user names and the corresponding passwords. It is then possible to change everything in the database. If the attacker injects malicious MySQL in the safe mode, then the text will be inserted into the database as string (see figure 44) and will not be executed as SQL command.

This part finishes with some last pieces of advice. If dynamic tables need to be created, then the user should not choose the table name. The reason is that PreparedStatement cannot be used to select tables. In this case, the table name should be number-based, e.g. t1, t2, t3, and so on. The advantage is that the input parameter can be tested with the java expression "t" +
In `tableId.toString()` as to whether it is an integer. If it is necessary for the user to choose a table name in the program, then the table id should be only mapped to a name in the MySQL tables. E.g. the entry in the MySQL tables: `tableId = 3, name = 'whatever'`, means that the name of user table is `whatever`.

### 6.5 Login mechanism in Tomcat

First of all, the tables shown in listing 142 should be created in the MySQL workbench. This

```sql
CREATE TABLE `tomcat_users` ( 
  `login` varchar(20) CHARACTER SET utf8 COLLATE utf8_bin NOT NULL,
  `password` varchar(32) CHARACTER SET utf8 COLLATE utf8_bin NOT NULL,
) PRIMARY KEY (`login`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1;

CREATE TABLE `tomcat_roles` ( 
  `role` varchar(20) CHARACTER SET utf8 COLLATE utf8_bin NOT NULL,
) PRIMARY KEY (`role`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1;

CREATE TABLE `tomcat_users_roles` ( 
  `login` varchar(20) CHARACTER SET utf8 COLLATE utf8_bin NOT NULL,
  `role` varchar(35) CHARACTER SET utf8 COLLATE utf8_bin NOT NULL,
) PRIMARY KEY (`login`, `role`),
KEY `tomcat_users_roles_foreign_key_2` (`role`),
CONSTRAINT `tomcat_users_roles_foreign_key_1` FOREIGN KEY (`login`) REFERENCES `tomcat_users` (`login`),
CONSTRAINT `tomcat_users_roles_foreign_key_2` FOREIGN KEY (`role`) REFERENCES `tomcat_roles` (`role`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1;

INSERT INTO `tomcatgwt` . `tomcat_users` ( `login`, `password`) VALUES ( 'Michael', '3e06fa3927cbdf4e9d93ba4541acce86' );
INSERT INTO `tomcatgwt` . `tomcat_roles` ( `role`) VALUES ( 'user' );
INSERT INTO `tomcatgwt` . `tomcat_users_roles` ( `login`, `role`) VALUES ( 'Michael', 'user' );
```

Listing 142: MySQL code to create the login tables.

means there is one valid user with the login Michael and the password Michael (a real program allows only passwords which have at least two small letters, two capital letters, two numbers, and two special signs like $ or §). Listing 143 displays the code which should be inserted after the line `<Realm className="org.apache.catalina.realm.UserDatabaseRealm" resource-Name="UserDatabase"/>` in the Server/server.xml file. The command `digest="md5"` means that the user passwords are saved as MD5 hash in the database. Passwords should be never stored in plain text in the database.

After the DA_TomcatGWT/WebContent/WEB-INF/web.xml file has been opened, the code shown in listing 144 should be inserted above `</webresource-collection>`. This means that only logins with the connected role name "user" get access to the web application. If there is a need for a special administrative site, then the role admin has to be added in the `tomcat_roles`
Listing 143: XML code registering users in Tomcat.

Listing 144: XML code which grants only users with the role "user" access to our web application.

table and the tomcat_users_roles table should give some user logins the role admin. This allows having sites, which grant only access to admin roles.

After the </security-constraint> line in the web.xml file, the code displayed in listing 145 should be entered. It is important to use a form based login and not the basic login mechanism

Listing 145: XML code setting up form based login mechanism.

as the basic one does not allow invalidating the user session and so no equivalent logout function exists. Finally, the login.jsp file where the user can enter its login name and password needs to be created. Listing 146 shows the JSP code. In the post form, the action value has to be set to j_security_check, in order to send the login to Tomcat. The login input field has to have the name j_username, and the password field the name j_password, so that Tomcat can extract the login and password values out of the post data. If the Tomcat server starts now and the URL https://localhost:8443/DA_TomcatGWT/TomcatGWT.html has been entered, then the user has to authenticate itself before it gets access to the GWT web application. Figure 45 shows the login screenshot. This means that attackers are not able to see any of the compiled JavaScript code, and so they have no information about the applications structure to find any vulnerability as shown in section 3.6.2 and figure 22. If the person does have the password, then it still has no rights to send or manipulate any GWT RPC calls in order to inject malicious SQL code, because Tomcat will block the RPC call. If Michael will be entered as login name and password, then access to the GWT website will be granted.

The GWT application will be extended so that it shows the login name of the logged-in user, and that it has a logout button. Firstly the users Maren, Oliver, and Stefan have to be added to
Listing 146: HTML and Java code of login.jsp file.

```html
<html>
<head>
<meta http-equiv="Content-Type" content="text/html; charset=ISO-8859-1">
<title>Login</title>
</head>
<body>
<% if(request.getParameter("fail") != null & & request.getParameter("fail").equals("true")) { %>
<br><h1>Login failed</h1>
<% } %>
<form method="POST" action="j_security_check">
Login name: <input type="text" name="j_username" />
Password: <input type="password" name="j_password" />
<input type="submit" value="Login" />
<input type="reset" value="Reset" />
<br/>
In order to use the GWT web application, make sure your browser's JavaScript engine is enabled.
</form>
</body>
</html>
```

the tomcat_users table. In this example the password for every user is the same as its login name, and every user has the same role name. The two functions String getLoginName and void logout have been added to the CountryService remote interface. The implementation of these methods is shown in listing 147.

```java
@Override
public String getLoginName() {
    return getThreadLocalRequest().getUserPrincipal().getName();
}

@Override
public void logout() {
    getThreadLocalRequest().getSession().invalidate();
}
```

Listing 147: Java code of getLoginName and logout functions.

The user can be logged out by invalidating the session as the application uses the form based login mechanism. This means that if the user calls the page the first time, then Tomcat gives

```sql
INSERT INTO `tomcatgwt`.`tomcat_users` (`login`, `password`) VALUES ('Maren', '144a85d15126fb1d41ef4e701d8a816c');
INSERT INTO `tomcatgwt`.`tomcat_users_roles` (`login`, `role`) VALUES ('Maren', 'user');
INSERT INTO `tomcatgwt`.`tomcat_users` (`login`, `password`) VALUES ('Oliver', '270907d414d151d7b25275c7d3d1d6a5');
INSERT INTO `tomcatgwt`.`tomcat_users_roles` (`login`, `role`) VALUES ('Oliver', 'user');
INSERT INTO `tomcatgwt`.`tomcat_users` (`login`, `password`) VALUES ('Stefan', '752b048c76633399b04f6e87a8b211ca');
INSERT INTO `tomcatgwt`.`tomcat_users_roles` (`login`, `role`) VALUES ('Stefan', 'user');
```

Michael von Wenckstern: Web Applications Using the Google Web Toolkit
it a HTTP session id for the login request (see figure 46). After a successful login, Tomcat
gives the browser a new session id, which it sends on every request to the server. The server
checks the browser rights based on the HTTP session id. This means if the session id is in its
session store, then the browser has access to the page; otherwise Tomcat denies the page access.
Invalidating the actual session removes the session id from the store and this will cause an access
deny (reloading the login form again) when the user sends any data to the server.

Finally, the TomcatGWT class has to be modified in such a way, that it calls the getLogin-
Name remote method in the onModuleLoad function and that it invokes the logout remote
method after the user has clicked at the logout button. Figure 47 shows a screenshot of the final
result.

The user password should always be sent encrypted over a secure HTTPS connection to the
server. If it is not done, then an attacker can read the plain password using a tool like [Wir]. The
best way is to secure the entire application traffic with HTTPS avoiding anybody being able to
spy into the user’s session id: it requires only a little bit more computer resources in modern
Intel Xeon PCs, but the security gain is large.

6.6 SafeHtml

This section has shown how the database can be protected against malicious SQL code before;
this part demonstrates how to protect the web application against HTML injection now. A new
GWT Java Project will be created to show some possible attacks and how they can be prevented.
Figure 48 illustrates the layout and result of this page, if the user enters the text shown in list-
ing 148 and presses the button, which will be wrongly shown in the unsafe method.

Listing 149 illustrates the most important part of the source code. The unsafe method simply
connects two String objects together. The safe method uses the SafeHtmlBuilder to escape the
user’s text inputs with the appendEscapedLines function.
Of course one may think the attacker can manipulate the browser’s DOM with Firebug anyway, why should the user’s inputs be escaped. The reason is quite easy: Imagine the user inputs have been saved in a database and the content will be loaded for every user on program start. If the HTML inputs are not escaped, then it can happen that every user can no longer use the GWT program, e.g. when the hacker injects an HTML redirect code.

A more detailed tutorial about SafeHtml can be found at [Goo10f].
Figure 48: Top picture shows the usage of the unsafe text insert method, which allows HTML injections.
Bottom picture shows the result when the programmer uses the SafeHtml interface to update its widgets.
7 Presenting a complex software application written in GWT

As mentioned in the introduction, a user-friendly client program which should save the research results of "Trip-Matrix-Composite" project of the TU Freiberg should be developed. The Java program, which satisfied the functional specification document in 2009, was finished in the middle of 2010. Figure 49 shows the old Java Swing version. Since the project structure with phase, partial project, process, and step was not flexible enough, the user decided to replace it with a tree based one. Satisfying this wish means changing the entire database structure. Because version 0.5 of the Java program did not support file uploads, there was no need for an extra server, and so all MySQL requests were saved into the JAR archive. This was a large security hole as it is relatively easy to change the SQL strings in a published JAR file. The entire database can be destroyed by changing a simple value Update query to a Drop schema one. This would result in a big disaster. These two above mentioned issues, together with the fact that the users had to update the program every month because it was still under development, were the reasons to rewrite the entire program as a web application. Because the program has to handle many user inputs, e.g. resizing rows, switching columns, and merging cells; one criterion was that most of the program runs in JavaScript on the client computer, and not on the server.

The question was now, whether this program should be implemented in JavaScript using jQuery, or in Java using GWT. One point in favor of the GWT toolkit was the impressive showcases of GXT (as mentioned in section 3.1). Another fascinating feature is the powerful GWT debugger, also that writing a GWT web application is very similar to writing a Swing one. However one point can be really annoying: The setup of a MySQL connection with the internal Jetty server. Changing the Jetty server code to allow SQL pools as shown in forums did not work. Creating an extra dynamic web project, which runs on Tomcat for the server-side part, and letting the GWT client part run on Jetty did not work either, because of Google's same origin policy, which meant that all remote calls failed. It took a long time to find out how the GWT development mode should run under Tomcat, as shown in section 6.2. Firstly, the web application was developed with GWT 2.4 and GXT 2.5. The advantage of this combination is that the GWTDesigner in Eclipse can be used to build views. After the update to GWT 2.5 and GXT 3.0 the declarative layout can be used; but the GWTDesigner does not support the GXT widgets anymore. Due to the examples in the GWT and GXT showcases it is easy to start programming with these two frameworks. Getting more detailed information, like handling own drag and drop events for the asynchronous tree grid to update the MySQL database is much more complicated, as no examples exist and so the GXT API has to be debugged. The advantage of all GWT based libraries is that the GWT compiler can only translate Java code and no byte code; this means there is always the opportunity to read the source code to find out when what event types are fired. Besides the many advantages of the GXT 3 library, it has one disadvantage in that it
contains many private and package functions, which are not easy to extend an existing GXT widget like the TabPanel one. This means creating the com.sencha.gxt.theme.base.client.tabs package structure in the SFB project and having to copy the entire TabPanel widget, just to add some special behavior like undocking tab items from the tab panel and open them into a separate window as shown in figure 50. The usage of the GWT 2.5 and GXT 3 framework was the right decision for the database client project.

This passage makes some remarks about the GWT framework. Something really positive is that the application can be debugged with Eclipse, and that the Eclipse plugin does a lot of code generation, e.g. the GWT Remote service. Less convenient is the fact that the compilation needs a long time when the project becomes large, even if the CPU has four processors. This is fine, as the web application can be tested in the development mode; but the web browser (tested with Firefox 16) needs a long time in reloading the website since the class validation needs very long for a large project. One of the drawbacks of GWT is the built in serialization mechanism, which sometimes causes unwanted behavior: (1) forgetting to add a Java type to the GWT’s whitelist, causing the server not to send an answer; (2) having not a zero argument constructor resulting in complex GWT error messages due to the errors in the generated code. And even worse: the GWT deserialization mechanism contains bugs\textsuperscript{45} when deserializing arrays or hash maps of the type java.io.Serializable.

The SFB web application showed that it was the right decision to write the project with the Google Web Toolkit, because the framework allows the creating of awesome web user interfaces which act really like a normal desktop app. Since the source code of the database web client (see figure A71) contains more than a million lines, this section shows only the two most interesting parts:

- How the project handled the copy-paste mechanism between the web application and Microsoft Office, and
- How to write an annotation processor using GWT deferred binding generator to show all desired UTF-8 block sings.

The next paragraphs explain how to enable normal copy and paste between the web application and other desktop ones. Firstly an HTML paste widget and a copy FocusPanel have to be created as shown in listing 150. The HTML attribute `contenteditable=""` is important because it allows the user to insert rich text with images and tables. At the beginning of the application, the visibility of both objects have to be set to false, and they have to be added to the RootPanel. The function `setCopyHTML` is shown in listing 151, and sets the HTML content to the copy

\textsuperscript{45}I published the bug at [Mica].
widget, so that the user will copy it with control + C into its clipboard. The markText func-

```java
private static final FocusPanel copy = new FocusPanel();
private static final HTML paste = new HTML("<div id="pasted1312012" contenteditable="\nstyle="width:100px;height:100px"></div>";
```

Listing 150: Java code showing the creation of the HTML paste widget and the copy FocusPanel.

```java
public static void setCopyHTML(String html) {
    copy.setVisible(true);
    HTML Html = new HTML();
    if (Window.Navigator.getUserAgent().toLowerCase().contains("safari")) {
        Html.setHTML("<div style="height:1px;width:1px">"+html+"</div>");
    } else {
        Html.setHTML("<div contenteditable="\nstyle="height:1px;width:1px">"+html+"</div>"); // must implement deferred binding, because in Chrome we cannot allow contenteditable, 'safari' should be selected (as it uses WebKit as Chrome).
    }
    copy.setWidget(Html);
    markText(Html.getElementById());
    copy.setFocus(true);
}
```

Listing 151: Java code of setCopyHTML method.

tion is copied from [z00]. The hideCopy function sets the visible attribute of the copy widget to false. The important part of the onKeyDown function in the TableView::TableController class is displayed in listing 152. In this function, the user’s key down event will be intercepted

```java
@Override
public void onKeyDown(KeyDownEvent event) {
    controlKeyDown = (event.getNativeKeyCode() == KeyCodes.KEY_CTRL) || event.isControlKeyDown();
    ...,
    if ((controlKeyDown || event.isMetaKeyDown()) && event.getNativeKeyCode() == 67) { // CTRL + C or COMMAND + C
        copyDataToClipboard();
    } else if ((controlKeyDown || event.isMetaKeyDown()) && event.getNativeKeyCode() == 86) { // CTRL + V or COMMAND + V
        pasteDataFromClipboard();
    }
}
```

Listing 152: Java code of onKeyDown function in the TableView::TableController class.

because it is called before the browser’s standard action has been invoked. If the user did not reconfigure the browser standard actions, then it will copy the selected content after the user has
pressed control + C. The `copyDataToClipboard` function creates a Microsoft Office compatible table with many specific style commands like `mso-number-format` (see [cos03] and [Micb]46).

The most important code is shown in listing 153. The paste version is the inverse to the copy one. This means if the user presses control + V, then the paste HTML widget is shown, the innerHTML is set to an empty string, and the focus is activated to it. After 100 ms the user inserts the content into the contenteditable widget, meaning the content can be received by reading the innerHTML value and the paste object can be hidden.

This section ends by showing how to create own annotations and how to process them, just like the Google’s `@Source` or `@ImageOptions` ones. First of all the annotation interfaces have to be defined as shown in listing 154. Annotation interfaces are defined with the `@interface` Java

```java
public @interface Block {
  int start();
  int end();
}
```

```java
public @interface UnicodeBlock {
  String name();
  Block[] unicodeBlocks();
}
```

```java
@Retention(RetentionPolicy.RUNTIME)
@Target(ElementType.TYPE)
public @interface UnicodeView {
  UnicodeBlock[] unicodeBlocks();
}
```

Listing 154: Source code showing how to define Java annotations.

46I have to download, extract the help file and open Style Attributes as shown in figure A72
keyword; and contain methods which have no parameter, do not throw any exception, and the return type is one of the following:

1. All primitive types like `byte`, `short`, `int`, ... but no wrappers like `Integer`
2. `String`
3. `Class`
4. All `enum` types
5. Other annotations
6. One dimensional array of the types 1. - 5.

The annotation in listing 154 can be used to generate a widget, which shows all the buttons of different Unicode blocks and handles their click events. Listing 155 displays the code how to create a view as shown in figure A73.

```java
@UnicodeView (unicodeBlocks = {
    @UnicodeBlock (name = "Kyrillisch", uniCodeBlocks = { @Block (start =1024, end =1154), @Block (start =1160, end =1299) }),
    @UnicodeBlock (name = "Griechisch_und_Koptisch", uniCodeBlocks = {
        @Block (start =890, end =1023)}),
    ...
})
public interface UnicodeCharView extends Display {
}
```

Listing 155: Source code showing how to use the self created annotations.

The advantage of using the annotations is that Unicode blocks can be easily added or removed. Naturally the same behavior could be achieved using a class and passing the wanted Unicode blocks as constructor parameters. The difference between these two methods is, that the HTML string containing all the buttons are created at

- Compile time when the annotation version is used or
- Runtime when the Java class version is used.

If there are 2000 UTF-8 signs, then the JavaScript code has to run a loop 2000 times to generate the HTML string. Since the buttons are created at runtime, the loop time is always saved, but the size of the *.cache.html files increases. As already explained in section 3.3.2, the following lines (see listing 156) have to be added to the module xml file.

```xml
<generate-with class="de.tu_freiberg.client.view.UnicodeCharViewGenerator"/>
<when-type-assignable class="de.tu_freiberg.client.view.UnicodeCharView"/>
</generate-with>
```

Listing 156: XML code defining the generator class which should handle the annotations.

The first plan was to create a large UiBinder file containing the declarative layout of the buttons, but I could not register the generated *.ui.xml file to the GWT resourceOracle (I asked this question at stack overflow [Mieb], but I did not get an answer as to how to solve this problem until March 12th 2013). Because section 3.3.2 already explained how to generate code with the GWT compiler deferred binding, this paragraph only describes the `createView` function of the `UnicodeCharViewGenerator` (full source code is available in listing A146) in listing 157.
Line 5 iterates over all classes or interfaces in the module. The next two lines check if the

```java
public void createView(String typeName, GeneratorContext context, SourceWriter sw) throws NotFoundException {
    sw.println("public Widget createView() { " ); sw.indent();
    int i = 0;
    for (JClassType type: context.getTypeOracle().getTypes()) {
        UnicodeView unicodeView = type.getAnnotation(UnicodeView.class);
        if (unicodeView != null) {
            for (UnicodeBlock unicodeBlock: unicodeView.unicodeBlocks()) {
                String StringBuilder sb = new StringBuilder();
                for (int unicode=block.start(); unicode <= block.end(); unicode++) {
                    sb.append("<button class='gwt-Button'>&# " ).append(unicode).append(";&lt;/button>");
                }
                sw.println("st.add(new com.google.gwt.user.client.ui.HTML (" + sb.toString() + ",\"+ unicodeBlock.name() + ",\"+ 20");");
                sw.println("DOM.setStyleAttribute(st.getHeaderWidget("+ i + ").getElement(),\"fontSize\",\"0.9em\")");
                sw.println("DOM.setStyleAttribute(st.getWidget("+ i + ").getElement(),\"overflowY\",\"scroll\")");
                i++;
                break;
            }
        }
    }
    sw.println("return st; ");
    sw.outdent(); sw.println("}");
```

Listing 157: Source code showing the `createView` function of the `UnicodeCharViewGenerator`.

interface or class is annotated with the `@UnicodeView` interface. Line 8 iterates over all `@UnicodeBlock` interfaces inside the `UnicodeView` annotation. The same thing is done in line 11. Line 12 creates the large HTML string using the `StringBuilder` class. The self-defined annotation interfaces can be used in the same way as normal Java ones. The usage of the `Generator` class in the deferred binding class also has some disadvantages:

- It is quite uncomfortable to write code: The code `sw.println()` has to be written every time, which reminds one of the HTML code generation in the Servlet era. It would be more convenient if the direct Java output code could be written into the file without the usage of the `println` command as the HTML code can be directly written in the JSP file. Another advantage of writing the generated code directly and without the usage of print functions, is that Eclipse can detect Java errors and the auto complete functionality would
work. Until now the output code is a string, which will not be checked and so syntax errors will only be noticed at compile time.

- The error messages when the programmer uses the annotations the wrong way are mostly confusing for users which do not understand the deferred binding process. Strange compiler errors occur when the code generation is successful, but the generated code cannot be compiled later on. As an effect of this, the GWT compiler generates a snapshot file, which contains the generated code. However this file can reference to other generated files, which are not available anymore. If this happens, then the -gen compiler option should be added to store all generated files in a separate folder. Copying some generated sub folders into the Eclipse source folder merges the Java files; this has the advantage that the Eclipse features are available, e.g. jumping to other classes by pressing the control key and click at any class or interface type.
8 Conclusions

8.1 Summary

In general it was possible to convert the Java program into a web application with the same behavior. The most important success factor was the widget offer of the different GWT based libraries like GXT. An equivalent widget exists for every Java Swing user interface component. Even lacking a certain widget behavior is not a problem as due to the available source code for all GWT based libraries, it is not difficult to extend any widget.

GWT’s powerful remote procedure mechanism was another reason for the success of the database web project because it works similarly to the Java RMI technology. This means the developer does not have to take care of the data serialization and the remote method invocation at all.

The Agricola Model-View-Presenter example showed that it is possible to create large scale applications in GWT. Google’s decision to choose the Model-View-Presenter pattern as default user interface design pattern makes it easy to create specific layouts for desktop, tablet, and mobile computers.

The JavaScript Native Interface allows importing different JavaScript libraries. This enables including the pdf.js library, which gives the user the opportunity to read PDF files without an extra Adobe plugin.

However, there are also limitations of the Google Web Toolkit. Deferred Binding uses the GWT as Java reflection replacement. This mechanism allows generating class specific properties, which uses e.g. the RPC mechanism to serialize the JavaScript objects to String values. Since the compiler creates the language or browser specific classes which are invoked by the bootstrap mechanism, there is no way to inspect Java variables and function names at runtime. This means GWT is not suitable for writing an integrated development environment like Eclipse, because these programs need to inspect private variable names in order to automatically generate getter and setter functions.

Other limitations of GWT are that only 2MB of model data can be stored in the URL or in the web storage and that the rich internet application has no direct access to clipboard data.

The answer to the question, whether it is possible to create a desktop-like web application in an efficient way with the Google Web Toolkit, can only be a partial yes. The reason is not that Google was not able to create a powerful framework. The answer to the problem cannot be completely positive, because the JavaScript engine does not have as much functionality as the Java Runtime Environment. Most of the missing JavaScript methods are not available due to security reasons. What I fail to understand is: Why does JavaScript not have access to the clipboard after pressing Ctrl+C or Ctrl+V, or why is the web storage or the URL length limited, despite Request for Comments (RFC) 2616 claiming "The HTTP protocol does not place any prior limit on the length of a URI" [R. ].

Perhaps the W3C committee will solve these two drawbacks of web applications soon. Ten years ago, nobody imagined that the new HTML5 and ECMAScript 5.1 would support drawing 3-D figures in web browsers using WebGL, uploading files per drag and drop with the FileReader class, opening sockets to receive messages from servers, or executing different threads using Web Workers.

This section finishes by giving some benefits and drawbacks of web applications. Websites have several advantages for the user over conventional desktop programs, such as access from anywhere with the internet. Data entered in web pages does not get lost if the local computer crashes because the information is stored on the server. Rich Internet Applications (RIAs) are more suited for tablets and phones as no installation is needed and the hard disk size is very small on mobile devices. Since most browsers execute websites in a sandbox and do not allow
them access to the client’s file system, internet pages cannot harm the user’s computer and are
preferred by many persons.

RIAAs also have advantages for developers. Bug fixing is a lot easier in websites because
there is no need to distribute any new version. Another benefit of web pages is not having to
deal with several versions, since the web browser always uses the latest version. The developers
are not forced to update their programs when a new Java runtime version appears; serialization
errors caused that the client software running on JRE 1.7 could not communicate with the server
running on JRE 1.6, and updating the server library to JRE 1.7 implies that every user also has
to update their JRE 1.6 to the newer one. Integrating other web services like amazon login is
much easier for web applications. The web page developer only has to force the web server to
use Transport Layer Security (TLS) and does not have to deal with encryption in detail. Since
software running on a server cannot be copied so easily, web applications are better protected
from piracy than desktop programs.

One disadvantage of internet pages is the loss of speed, as JavaScript code is slower than
native codes like Java, C++ or Adobe Flash. The user loses control over its data because it
is not known what companies do with the uploaded files. Websites may become very slow at
prime time, when many users cause the server to be overstretched. As mentioned above, desktop
programs have better user experiences.

More information about advantages or disadvantages of web and desktop applications can
be found at [And08].

8.2 Future work

The comparison of the execution speed showed that the Java program multiplying two 1000x1000
dimensional matrices is only slightly faster than the corresponding GWT application running
in Chrome. The test also presented big differences in the execution speed of different web
browsers. One future work could investigate the JavaScript code compared to the browser’s ex-
cution time. An interesting topic would be how the browsers deal with the new JavaScript Web
Workers; do they really open a new thread, or is the code only running scheduled on the same
core.

Khronos announced WebCl [Khr] allowing JavaScript to run on the Graphics processing unit
(GPU). This must also be compared to the Java GPU support using Aparapi [AMD] or the AMD
& Oracle Sumatra project [Ora12] which might be available in Java 9. Intel also published a
prototype of its RiverTrail [Int] project, allowing JavaScript to run on several cores and to use
hardware vector instructions. My guess is that JavaScript will become more and more powerful,
and in a few years nearly every application can run in the web browser. This means JavaScript is
the new assembler, and the web browser is the new operating system. Nowadays, the JavaScript
library pdf.js [Moz03b] can already replace the Adobe Reader, zip.js [Gil02] can zip and unzip
files, Doppio [CJ 01] is an approach letting JavaScript interpret JVM byte code to execute Java
programs in the web browser without needing an installed Java version on the local PC, and
Shumway [Moz03a] is Mozilla’s new JavaScript project emulating the Flash VM to allow tablet
users to play existing flash games.
A Appendix

A 1 Configure the Google Web Toolkit framework in Eclipse

A 1.1 Install the Java Developer Kit

The latest Java JDK version can be downloaded at [Oraa].

After the License Agreement has been accepted, the Java version for computer can be downloaded. It is important to install jdk-7u21-windows-x64.exe file for any 64bit Windows version. The system type (32-bit or 64-bit Operating System) can be found at ControlPanel -> System and Security -> System.

If the Java installation has been successful, then the DOS command java -showversion prints a message as displayed in listing A1; otherwise an error message as demonstrated in listing A2 will be shown.

```
1 w: \> java -showversion
2 java version "1.7.0_05"
3 Java(TM) SE Runtime Environment (build 1.7.0_05-b06)
4 Java HotSpot(TM) 64-Bit Server VM (build 23.1-b03, mixed mode)
```

Listing A1: Java installation succeeded.

```
1 w: \> java -showversion
2 'java' is not recognized as an internal or external command,
3 operable program or batch file.
```

Listing A2: Java installation failed.

A 1.2 Download Eclipse

The Eclipse IDE for Java EE Developers is available at [Fl]. It is important to download and unpack the Enterprise Edition (EE) as illustrated in figure A1, because the GWT plugin cannot be installed in the standard edition.

![Figure A1: Download Eclipse IDE for Java EE Developers.](image)

If the host computer has a lot of RAM, then it is useful to add the following options -Xms400m and -Xmx5120m into the eclipse.ini file.

A double click at eclipse.exe opens the IDE. The best way is to create a workspace folder in the eclipse one in order to have all the files and configurations at one central place. After the initial start, the workspace has to be chosen as displayed in figure A2.

A 1.3 Install the GWT plugin in Eclipse

Since the GWT compiler interprets the files as UTF-8 encoded, the Text File Encoding (Window -> Preferences -> General -> Workspace -> Text File Encoding -> Other: UTF-8) should be changed to UTF-8.

This paragraph describes how to install the GWT Eclipse plugin. Firstly, the menu Help -> Install New Software ... should be opened. Secondly, the Add ... button has to be clicked to
Figure A2: Screenshot of Eclipse file structure and dialog of Workspace Launcher.

insert the GWT repository as shown in table A1. Thirdly, the entries Google Plugin for Eclipse, GWT Designer for GPE, and SDK as displayed in figure A3 should be selected. All security warnings during the installation process have to be accepted with the OK button.

Table A1: Add GWT Plugin repository.

<table>
<thead>
<tr>
<th>Name:</th>
<th>GWT Plugin</th>
</tr>
</thead>
<tbody>
<tr>
<td>Location:</td>
<td><a href="http://dl.google.com/eclipse/plugin/4.2">http://dl.google.com/eclipse/plugin/4.2</a></td>
</tr>
</tbody>
</table>

Figure A3: Selected entries of the GWT Eclipse plugin, which should be installed.

This passage explains how to install the GWT Designer Eclipse plugin. First of all the Install New Software dialog should be opened and the GWT Designer repository has to be added as shown in table A2. It is sufficient to install the GWT Designer and the WindowBuilder Engine as illustrated in figure A4.

A 1.4 Create first GWT Java Project

Firstly, a new GWT Java Project (File -> New -> Project ... -> WindowBuilder -> GWT Designer -> Model -> GWT Java Project) should be created. Secondly, "FirstProject" should be entered as name for this GWT project as shown in figure A5. Thirdly, check the option Create GWT module as displayed in figure A6. After the project has been created, figure A7 illustrates how the project can be executed as Web Application. Later on, an arbitrary browser opens the URL http://127.0.0.1:8888/ImageViewer.html?gwt.codesvr=127.0.0.1:9997.

Michael von Wenckstern: Web Applications Using the Google Web Toolkit
Table A2: Add GWT Designer Plugin repository.

<table>
<thead>
<tr>
<th>Name:</th>
<th>GWT Designer Plugin</th>
</tr>
</thead>
<tbody>
<tr>
<td>Location:</td>
<td><a href="http://dl.google.com/eclipse/inst/d2wbpro/latest/4.2">http://dl.google.com/eclipse/inst/d2wbpro/latest/4.2</a></td>
</tr>
</tbody>
</table>

Figure A4: Selected entries of the GWT Designer Eclipse plugin, which should be installed.

The first time a GWT project is opened in a web browser, the Google Web Toolkit Developer Plugin has to be installed. Figure A8 shows the screenshot on how to download and install this browser plugin. After the plugin has been installed and the browser has been restarted, the GWT web application is available. A click on the button opens a pop-up window. A click at the red square icon (shown in figure A9) in the development mode stops the web application. The GWT Java project can also be launched in debug mode (right click at FirstProject -> Debug As -> Web Application). A breakpoint (displayed as blue circle) can be set by double clicking at the left frame in the source code window as illustrated in figure A10. The web browser should load the same URL as in the paragraph above. A click at the button intercepts the web application execution and opens the debug mode at the previous set breakpoint position.

Figure A11 displays how to compile the GWT project to JavaScript and HTML. The GWT compiler options `-localWorkers 4` says that four threads are used in the compilation process. It is advisable to use as many threads as the computer has physical cores. The compilation result is available at the war folder as shown in figure A12. Opening the ImageViewer.html file executes this web application.
Figure A5: Properties of GWT project.

Figure A6: Create GWT module in FirstProject.
Figure A7: Right click at FirstProject opens popup menu. The menu entry Run As -> Web Application should be selected.

Wenger-Bunche
Thu Feb 19 00:00:00 CET 2013
Tomorrow’s headie. Wenger won’t have been an easy manager at times as fans have suggested. There will be many who will also see the positives. Wenger has been an important part of Arsenal’s history.

Jack the hat
Thu Feb 19 00:00:00 CET 2013
Unoubtedly, Wenger is probably still the greatest manager ever for Arsenal. It would be hard to see the day he leaves the club. he has managed to take an underdog side into the top tier. Arsenal fans knocking the man should remember that the reason only Arsenal are considered such a force in England is the man himself. If you expect the team to win and play good football, because he has set them to those high standards, I understand the disheartening for the clubs, players and fans alike for a club like arsenal when you dont win anything for close to 5 years, but its imperical now to lose faith. Good luck in the future mister.football

A United Fan
Can’t wait to watch Bayern thrash arsenal in the cl this time. their only chance of a trophy in the cup

’am bon 2012
Thu Feb 19 00:00:00 CET 2013
Arsenal are the only club stupid enough to make wenger the highest paid manager in thepl on £7 million a season when he has won nothing since 2005!

Manu1999Triple
Thu Feb 19 00:00:00 CET 2013
If wenger go, it will be the same as muscat (chelsea) and martin allis (arsenal) bosses in one year

duff
Thu Feb 19 00:00:00 CET 2013
Also in this funny way Arsen FC is one story and Aramere Wenger it’s another story, the media and generally all football fans I love reading about the Arsenal story and Wengers_IP is friend more than Arsenal

Gunsandshells
Thu Feb 19 00:00:00 CET 2013
Arsene is a top top manager no doubt about that, but I think he contributes to his problems, the sales of Cesc, RVP, Ebue and so many to mention he not invent player quality players, rather Arse buy average or no name players. People RVP in mind but why we wait for that to come he should have done the same with some good player. and I think he has break the heart of all Arsenal fans in the past. We have won a lot to with the young talent on loan and ship out the 2 poles and the deadwood like Djourou and co. But the man always defends his players in good and bad times.

ur_nightmare
Thu Feb 19 00:00:00 CET 2013
lived. Wenger has done a great job in keeping Arsenal where they are now and until the owners allow Wenger to bring in quality player, the results will not just be going to happen.

Manu1999Triple
Thu Feb 19 00:00:00 CET 2013
If Wenger was to get the boot, i can’t see there being any other manager out there, that can do what he has done in terms of keeping Arsenal in and around the top 4/5 positions.

Jeansellolland
Thu Feb 19 00:00:00 CET 2013
he will be just a little MANAGER I asked THE BOARD

what will I GET? IT WILL BE MONEY

Qwa WENGER, WENGER,
Thu Feb 19 00:00:00 CET 2013
Whatever will be, will be but Arsenal is showing the world that they have the best manager in the world. That’s why the pressure on them is more... Bayern Munich BOOM The End

gunners
Thu Feb 19 00:00:00 CET 2013
The pressure for him to have come from the media and punters who influence week mind! Will the pressure really mount, if we can’t beat Bayern? All the expert are saying we can’t win, so where the pressure? Definitely we do need to beat Villa

If we win 6-0 tonight, it will not make us forget for giving away a chance at the PL cup. Wenger (not Kroalewitz, God is on Wood) made the decision to start with some reserves and he has done so many times before. As we saw in the FA Cup, when turning a winning team into a losing one.

Almost every season we have competed in the Champions league, we have come off at the stage where Wenger starts rotating the squad too much.

Time for Wenger to move players and give someone new a chance. My money is on David Moyes.

johnkelevi123
Thu Feb 19 00:00:00 CET 2013
Yes Ars, But the Sharehold dies will miss you even more!

Why am I suddenly getting the feeling that AW thinks he is God’s gift to Arsenal? I have admired the man for what he HAS done for Arsenal BUT......that was then this now. He has proven himself for the past 9 years and Arsenal have nothing and although I never believe in manager should always take the kids to what happens in the field, a manager MUST have one thing and that is motivation. It seems to me that he has lost this skill and the players go on selflessly on may wheal they believing THEY are somebody special. Well, either AW is wrong OR the players are. I think its AW.

Mr Kepping
Thu Feb 19 00:00:00 CET 2013
AW, you will NOT be missed when you are gone. ALL managers must go sometime and I think you should get used to the idea that your days over. I have watched Arsenal since i was 15 when Tom Whistle was manager and i recall none of them stayed as long as AW. There is the problem. AW is no longer the man or the manager he was and it is time to go but HC doesn’t want to. He MUST consider the fans, they are the ones who week after week wonder if they are going to win their next game. That is wrong. AW has to do all with himself and answer a list of questions about himself and all those that come from the fans. Most of them have to do with the fans. The fans come first - they always have. However, AW must also understand that what he HAS done for Arsenal in the golden years cannot sustain the reputation. Football lives from one season to another and it is time that AW realised that his time has come.

Mahatma Gandhi
Thu Feb 19 00:00:00 CET 2013
@przemekaye this media players a sorry under, the same one that lost England hosting the World cup. They drive on negative reporting (as it sells more). Wenger may not be winning now but he is one of the best managers, but like any human he had the pressure and the media guys are making him feel it more, but only till he finds a treatment of himself as a threat to @przemekaye and which real gunners??

R 1 Lists

R 1.1 List of Tables

1. Most important HTML tags ........................................... 4
2. Overview of GWT toolbox ............................................. 13
3. Passing JavaScript values into Java code .......................... 15
4. Passing Java values into JavaScript ................................. 16
5. Parameter signature of most common Java types .................. 16
6. Dead code elimination grouped in different steps ................. 33
7. Examples to show the difference of String::match in the Java vs. JavaScript world. ............................................. 39
8. HTTP status codes ..................................................... 58
9. GWT application’s URL of different program states ............... 62
10. Steps how to create a new Server in Eclipse ...................... 119
11. Dynamic Web Project wizard part 1. ................................. 119
12. Dynamic Web Project wizard part 2. ................................. 120
13. GWT module properties ............................................... 120
14. Wizard Run Configurations ............................................ 121
15. Wizard showing up when Tomcat is started the first time .......... 121
16. Wizard Adding new user ................................................. 126
17. Wizard creating New Connection ..................................... 127
18. Example how to inject MySQL code into the unsafe function ... 131
A1. Add GWT Plugin repository. ......................................... A 2
A2. Add GWT Designer Plugin repository. ............................... A 3
A3. Overview of all ASTNode types, this table lists the corresponding classes instead of the direct types .............................. A 310
# 1.2 List of Figures

1. CSS example ........................................ 6
2. Simple JavaScript calculator example .......................... 7
3. HTML DOM of listing 3 .................................. 9
4. Files the compiler generated ................................ 19
5. Loading sequence of a website .............................. 24
6. General steps of the GWT compiler ...................... 28
7. General steps of pre compilation process ............. 29
8. General steps of one compilation permutation ......... 30
9. Optimization order in `optimizeLoop` .................. 32
10. Control flow graph of liveness analysis ............ 37
11. Simple example code for using no JREE class ....... 38
12. Widget class hierarchy ................................ 40
13. Label widget class hierarchy ......................... 41
14. FocusWidget widget class hierarchy ................ 42
15. DateBox composite contains TextBox, PopupPanel and DatePicker widgets ....... 43
16. Composite widget class hierarchy ..................... 43
17. The own Composite widget ............................ 43
18. Panel widget class hierarchy ........................... 45
19. General handler interfaces ............................. 48
20. Special handler interfaces ................................ 49
21. Calls and messages of an invoked Remote Procedure Call ........................................ 52
22. HTTP post result manipulated in IE debugger ........ 62
23. Screenshot of CSS transition navigation menu .... 69
24. ImageResource as background picture .................. 74
25. Model-View-Controller pattern .......................... 75
26. MVC pattern for server intensive web applications .... 76
27. Taligent Model-View-Presenter pattern ................. 77
28. Dolphin Smalltalk Model-View-Presenter pattern .... 78
29. Screenshot of Agricola board game ...................... 79
30. Mobile view of Agricola board game ..................... 89
31. Screenshot of JSF version in category 1 ............... 100
32. Screenshot of Topic.jsf page .......................... 107
33. Screenshot of JSF chat application ..................... 111
34. Points earned by GWT and JSF in categories 1 to 5 .... 118
35. Servers directory in Eclipse ............................ 119
36. Screenshot how to compile the GWT project ........... 120
37. Screenshot of build path configuration ............... 122
38. Screenshot showing how to terminate the Development Mode ................................ 122
39. Screenshot of Tomcat's publishing settings ............ 123
40. Screenshot showing how to open the TomcatGWT connection in the MySQL Workbench ............ 126
41. Schema Privileges of TomcatGWT user .................. 127
42. Screenshot of remote database result ............... 130
43. MySQL injection shows secret database login .......... 131
44. Safe function prevents MySQL injections ............. 131
45. Screenshot of login formula ............................ 135
46. Screenshot of Tomcat's session id in Firefox .......... 135
47. Screenshot of final result with logout button .......... 135
48 HTML injections in unsafe text insert method, no injection by usage of SafeHtml. 137
49 Screenshot of old Java version of the SFB799 database client 138
50 Screenshot showing the extended TabPanel allowing to undock TabItems 139
A1 Download Eclipse IDE for Java EE Developers. A 1
A2 Screenshot of Eclipse file structure and dialog of Workspace Launcher. A 2
A3 Selected entries of the GWT Eclipse plugin, which should be installed. A 2
A4 Selected entries of the GWT Designer Eclipse plugin, which should be installed A 3
A5 Properties of GWT project A 4
A6 Create GWT module in FirstProject A 4
A7 Right click at FirstProject opens popup menu. The menu entry Run As -> Web Application should be selected. A 5
A8 Screenshot of how to install the GWT Developer Plugin in Firefox 20 A 5
A9 Left click at the right icon terminates the web application. A 5
A10 Double click at the left frame in the source code window creates a breakpoint, which is displayed as blue circle. A 6
A11 Screenshot showing how to compile the GWT project A 6
A12 War folder contains the result of the compilation process. A 6
A13 First website A 7
A14 Screenshot of the homepage of the Technische Universität Freiberg A 7
A15 Screenshot of ECMAScript Language test262 with Internet Explorer 10 A 8
A16 Screenshot of ECMAScript Language test262 with Chrome 26 A 9
A17 Screenshot of ECMAScript Language test262 with Firefox 20 A 10
A18 Screenshot of DOM manipulating demonstration A 11
A19 Screenshot of AJAX example, part I A 12
A20 Screenshot of AJAX example, part II A 13
A21 Screenshot of the web interface to paint pictures. A 13
A22 Screenshot of GWT showcase testing Stack Panel component A 14
A23 Screenshot of GXT showcase testing advanced toolbar component A 15
A24 Screenshot of GXT showcase testing border layout A 16
A25 Screenshot of GXT desktop showcase A 17
A26 Screenshot of youtube video playing Quake 2 in the web browser A 17
A27 Screenshot of youtube video testing mgwt showcase on an iPhone simulator A 18
A28 Picture showing interactions between GWT and Google Maps API V3 A 18
A29 Screenshot of generated website by Eclipse A 18
A30 Screenshot of type conversion in JavaScript A 18
A31 Screenshot of JSNI example A 19
A32 Screenshot testing wrapped syntaxhighlighter JavaScript library in GWT A 19
A33 Screenshot testing deferred binding with replacement A 20
A34 Screenshot testing deferred binding with generator A 20
A35 Eclipse Java AST of listing A20, part I A 21
A36 Eclipse Java AST of listing A20, part II A 22
A37 Eclipse Java AST of listing A20, part III A 23
A38 Eclipse Java AST of listing A20, part IV A 24
A39 Inheritance pattern for AST A 25
A40 Double dispatch pattern for AST A 25
A41 Example how to use Eclipse AST library together with visitor pattern A 26
A42 CompilerOptions class attributes A 27
A43 UML diagram of Java Runtime Environment Emulation (JREE) A 28
A44 UML diagram of java.lang package of JREE A 29
| A45 | UML diagram of java.util package of JREE .......... | A 30 |
| A46 | Operation interfaces of GWT widget hierarchy .......... | A 31 |
| A47 | Screenshot of FocusWidget example .......... | A 32 |
| A48 | Screenshot of Composite example, part I .......... | A 33 |
| A49 | Screenshot of Composite example, part II .......... | A 34 |
| A50 | Screenshot of Panel example .......... | A 35 |
| A51 | Screenshot of EventHandler example .......... | A 36 |
| A52 | Screenshot of DOMManipulation example .......... | A 36 |
| A53 | Screenshot of creating view in GWT Designer .......... | A 37 |
| A54 | Screenshot of UIBinder example .......... | A 37 |
| A55 | Screenshot of RMI example .......... | A 38 |
| A56 | Screenshot of Survey example, first page .......... | A 38 |
| A57 | Screenshot of Survey example, second page .......... | A 39 |
| A58 | Screenshot of Survey example, third page .......... | A 40 |
| A59 | Screenshot of Survey example after back button has been clicked .......... | A 40 |
| A60 | Screenshot of Firefox when it has to load all LaTeX icons from the server .......... | A 41 |
| A61 | Screenshot of Firefox when it shows the LaTeX icons from the inlined ClientBundle interface .......... | A 41 |
| A62 | Screenshot of Firefox when it shows the LaTeX icons from the ClientBundle interface with disabled inlining option .......... | A 42 |
| A63 | Screenshot of IE 10 without the usage of conditional CSS .......... | A 42 |
| A64 | Screenshot of IE 10 with the usage of conditional CSS .......... | A 42 |
| A65 | Screenshot of Google Chrome with the usage of conditional CSS .......... | A 43 |
| A66 | Screenshot of Firefox with the usage of conditional CSS .......... | A 43 |
| A67 | Model classes .......... | A 44 |
| A68 | Presenter classes .......... | A 45 |
| A69 | UML diagram displaying the AppController’s links to the other presenters .......... | A 46 |
| A70 | Screenshot illustrating the topic entries of "Comments on: You’ll miss me when I’ve gone" .......... | A 47 |
| A71 | Screenshot of the new SFB799 web application .......... | A 48 |
| A72 | Screenshot of Microsoft Office specific style definitions in the help file .......... | A 48 |
| A73 | Screenshot of widget which gets generated depending on the used Java annotations .......... | A 49 |
R 1.3 List of Listings

1. CSS example
2. Simple JavaScript calculator example
3. Simple HTML code for DOM model
4. HTML code of DrawDomExample.html (line 21)
5. HTML code of DrawDomExample.html (lines 30-41)
6. HTML code of DrawDomExample.html (lines 90, 95, 109, 111, 121)
7. HTML code of DrawDomExample.html (lines 147-151)
8. Excerpt from auto generated example source code by Eclipse
9. JSNI implementation of `window.alert`
10. Excerpt from code showing typing conversion in JavaScript
11. Excerpt from ImageViewer.html
12. Example code using syntaxhighlighter_3.0.83 library
13. Corresponding JavaScript code of the HTML code in listing 13
14. SyntaxHighlighterImpl.java in LoadJavaScript library’s project
15. Example JavaScript code choosing the right language
16. Status.java in deferred binding with replacement project
17. StatusLabelIE9.java in deferred binding with replacement project
18. StatusLabelFF.java in deferred binding with replacement project
19. ImageViewer.gwt.xml in deferred binding with generator project
20. StatusGenerator.java in deferred binding with generator project
21. Compiler output in deferred binding with generator project
22. HTML example describing the order of loading a web page
23. Prototype implementation of the `accept` method
24. Main.java in AST project
25. ASTRenamer.java in AST project
26. Multi-catch block
27. Single-catch block
28. Uncombined case labels
29. Combined case labels
30. Same parameter value optimizer: before
31. Same parameter value optimizer: after
32. Enum ordinalizer optimizer: before
33. Enum ordinalizer optimizer: after
34. Simple dataflow analysis example
35. Source code of UnreachableAnalysis.class
36. Source code of UnreachableIntegratedTransformationFunction.class
37. Simple copy analysis example
38. Simple example code for liveness analysis
39. Simple example code for using no JREE class
40. Source code of a quote function for regular expressions in JS and Java
41. Example project for own login composite widget
42. Very simple example of registering a ClickHandler
43. Example how to handle click events of many buttons
44. Manipulating the widget’s border style with GWT Style class
45. Manipulating the widget’s border style with GWT DOM class
46. listBox in XML
47. listBox in Java
50  Styled HTML in XML  
51  Styled HTML in Java  
52  Example how to get access to the widgets defined in the XML  
53  Exception of RmiClient.java  
54  Loading car informations using synchronous RMI calls  
55  Loading car informations using asynchronous RMI calls  
56  Generated CalendarService.java file by Eclipse  
57  Generated CalendarServiceAsync.java file by Eclipse  
58  Generated CalendarServiceImpl.java file by Eclipse  
59  Modified web.xml file by Eclipse  
60  Implementation of CalendarServiceImpl’s get method  
61  Invoking remote calls to collect more date information  
62  CalendarServiceImpl’s get method throws exceptions now  
63  Source code of Result.java  
64  Using the abstract Result class instead of AsyncCallback  
65  Source code of Survey.java (lines 129-141)  
66  Source code of Survey.java (lines 175-181)  
67  Source code of Survey.java (lines 189-205)  
68  Source code of IconsURL class  
69  Source code of IconsClientBundle class  
70  Java code of TransitionNavigation interface.  
71  Java code of IconsClientBundle class (ClientBundle.enableInlining=false)  
72  Java code of ScalableImage class  
73  Example code how to use the ScalableImage class.  
74  CSS code of transitionNavigation.css file  
75  Java code of TransitionNavigation interface.  
76  HTML code of navigation.html text file  
77  Java code of Resources interface.  
78  Java code of CSS entry point class.  
79  CSS parameterized with menuWidth and menuWidthInner  
80  Saving CSS parameter in Java file  
81  Using conditional CSS to deliver only browser-specific CSS  
82  Adding ImageResource function bgImage() to Resource interface.  
83  Adding ResourceImage object into CSS file  
84  UiChild annotation in TooltipImage  
85  Call the addTooltip method in any UiBinder file  
86  Code example how to create a model in the UiBinder  
87  BigAcquisitionsPresenter class  
88  Source code of registerHandlers and hideAcquisition implementations  
89  Source code of classes GetBigAcquisitionEvent, GetBigAcquisitionHandler, and HasGetBigAcquisitionHandler  
90  Source code of EventBus class.  
91  Source code of onGetBigAcquisition method in the AppController class.  
92  Source code of registerHandlers method in Rounds1To7View.java file.  
93  Source code of registerHandlers method in PlayerField.java file.  
94  Source code of ViewFactory class.  
95  Source code parts of DesktopViewFactory class.  
96  Source code fragments of MobileViewFactory class.  
97  Source code showing how to create presenters in AppController class.  
98  Source code defining the deferred binding for the different ViewFactories.
