Synthesis and (spectro)electrochemistry of mixed-valent diferrocenyl–dihydrothiopyran derivatives†

Konrad Kowalski,**a Rafał Karpowicz,a Grzegorz Młoston,b Dominique Miesel,c Alexander Hildebrandt,c Heinrich Lang,c Rafał Czerwieniec and Bruno Therrien†

Three novel diferrocenyl complexes were prepared and characterised. 2,2-Diferrocenyl-4,5-dimethyl-3,6-dihydro-2H-thiopyran (1, sulphide) was accessible by the hetero-Diels–Alder reaction of diferrocenyl thioketone with 2,3-dimethyl-1,3-butadiene. Stepwise oxidation of 1 gave the respective oxides 2,2-diferrocenyl-4,5-dimethyl-3,6-dihydro-2H-thiopyran-1-oxide (2, sulfoxide) and 2,2-diferrocenyl-4,5-dimethyl-3,6-dihydro-2H-thiopyran-1,1-dioxide (3, sulfone), respectively. The molecular structures of 1 and 3 in the solid state were determined by single crystal X-ray crystallography. The oxidation of sulphide 1 to sulfoxide 2, plays only a minor role on the overall structure of the two compounds. Electrochemical (cyclic voltammetry (= CV), square wave voltammetry (= SWV)) and spectroelectrochemical (in situ UV-Vis/NIR spectroscopy) studies were carried out. The CV and SWV measurements showed that an increase of the sulphur atom oxidation from −2 in 1 to +2 in 3 causes an anodic shift of the ferrocenyldikation-based oxidation potentials of about 100 mV. The electrochemical oxidation of 1–3 generates mixed-valent cations $1^+–3^+$. These monooxidised species display low-energy electronic absorption bands between 1000 and 3000 nm assigned to IVCT (= Inter-Valence Charge Transfer) electronic transitions. Accordingly, the mixed-valent cations $1^+–3^+$ are classified as weakly coupled class II systems according to Robin and Day.

Recently, mixed-valent (= MV) species have attracted considerable attention in particular in the field of molecular electronics as they offer the possibility to act as model compounds for molecular wires, switches and other electronic building blocks.1–15 Besides these foreseen technological applications MV compounds are used in electron transfer studies and are of key importance in biological systems.16–20

Ferrocenyl groups are often used in organometallic chemistry as redox-active terminal units, because ferrocene is thermally stable in its neutral and oxidised form.21 In addition, ferrocenyl/ferrocenium groups in mixed-valent species show an excellent electrochemical reversibility of the Fe(II)/Fe(III) redox couple, i.e. 2,5-diferrocenyl five-membered heterocycles.8,36,40

The electron transfer between the Fe(II)/Fe(III) centres, i.e. from the donor (Fe(II)) to the acceptor (Fe(III)) ion, manifests itself by the appearance of characteristic absorptions, i.e. IVCT (= Inter-Valence Charge Transfer) bands in the near infrared [NIR] spectral range.8,23

Two distinct modes of the electronic communication between the donor and acceptor metal centres in the MV state exist: “through bond” and “through space”.5,6,34 The “through bond” mechanism is characteristic for molecules in which π-conjugated connectivities are linking the two redox-active metal termini,5,6 while the “through space” mechanism requires a close proximity of the interacting centres.34 Depending on the degree of the electronic communication, three classes of MV complexes are distinguished according to the Robin and Day classification: non-coupled (class I), weakly-coupled (class II) and fully delocalized (class III) systems.35

Based on the linking group constitution, five structural types of dinuclear transition-metal compounds are known (types A–E), as schematically shown in Fig. 1.

Among the type A and type B molecules (Fig. 1), the respective diferrocenyl-functionalized systems have been extensively studied,5,6,36,40–42 whereas compounds of structural type D

The synthetic methodologies for the preparation of 2,2-diferrocenyl-4,5-dimethyl-3,6-dihydro-2H-thiopyran (1, sulphide), 2,2-diferrocenyl-4,5-dimethyl-3,6-dihydro-2H-thiopyran-1-oxide (2, sulfoxide) and 2,2-diferrocenyl-4,5-dimethyl-3,6-dihydro-2H-thiopyran-1,1-dioxide (3, sulfone) are shown in Scheme 1. Sulphide 1 was prepared via the hetero-Diels–Alder cycloaddition of diferrocenylthioketone50,51 with 2,3-dimethyl-1,3-butadiene in a sealed glass-tube at 75 °C (Experimental section).52 After appropriate work-up, compound 1 was obtained as a red solid in 65% yield. Treatment of sulphide 1 with hydrogen peroxide (30%) and selenium dioxide as oxidising reagents53 in methanol gave the respective sulfoxide 2, which was purified by column chromatography in 87% yield (Experimental section). Further oxidation of 2 with m-chloroperoxybenzoic acid (= MCPBA) in dichloromethane produced the S-atom reactivity allows us to synthesise three closely related derivatives 1–3 and investigate the influence of the different electron-withdrawing character of the aliphatic bridge on the IVCT properties of the mixed valence species 1⁺–3⁺.

Results and discussion

Synthesis

The synthetic methodologies for the preparation of 2,2-diferrocenyl-4,5-dimethyl-3,6-dihydro-2H-thiopyran (1, sulphide), 2,2-diferrocenyl-4,5-dimethyl-3,6-dihydro-2H-thiopyran-1-oxide (2, sulfoxide) and 2,2-diferrocenyl-4,5-dimethyl-3,6-dihydro-2H-thiopyran-1,1-dioxide (3, sulfone) are shown in Scheme 1. Sulphide 1 was prepared via the hetero-Diels–Alder cycloaddition of diferrocenylthioketone50,51 with 2,3-dimethyl-1,3-butadiene in a sealed glass-tube at 75 °C (Experimental section).52 After appropriate work-up, compound 1 was obtained as a red solid in 65% yield. Treatment of sulphide 1 with hydrogen peroxide (30%) and selenium dioxide as oxidising reagents53 in methanol gave the respective sulfoxide 2, which was purified by column chromatography in 87% yield (Experimental section). Further oxidation of 2 with m-chloroperoxybenzoic acid (= MCPBA) in dichloromethane produced
sulfone 3 at ambient temperature in 21% yield (Scheme 1, Experimental section).54

Compounds 1–3 are red solids soluble in common organic solvents. All three compounds are stable towards air and moisture in the solid state and in solution.

Compounds 1–3 were characterised by IR and NMR (1H, 13C{1H}; for more details see Fig. S1–S3, ESI†) spectroscopy and high-resolution mass spectrometry. The molecular structures of 1 and 3 in the solid state were determined by single crystal X-ray diffraction analysis. Electrochemical investigations were carried out by using cyclic voltammetry (= CV), square wave voltammetry (= SWV) and in situ UV-Vis/NIR spectroelectrochemistry.

X-ray structure determination

Single-crystals of 1 and 3 suitable for a single crystal X-ray diffraction analysis were obtained by slow diffusion of hexane into a dichloromethane solution of 1 and by slow diffusion of hexane into a diethyl ether solution of 3. ORTEP diagrams of 1 and 3 are shown in Fig. 2, while selected bond distances (Å) and angles (°) are listed in Table 1. Crystal and structure refinement data are presented in the ESI (Table S1†).

Compound 1 crystallizes in the orthorhombic space group Pcab, while complex 3 crystallizes in the triclinic space group P1. In the crystal packing of 3, two independent molecules (A and B) are observed. The structure analysis of both molecules confirmed the expected structures in which the two ferrocenyl groups are bonded to a sulphide (1) or a sulfone (3) moiety (Fig. 2). All ferrocenyl units show an eclipsed conformation with nearly equivalent distances between Fe and the centroid of the cyclopentadienyl rings (Table 1).

The oxidation of sulphide 1 to sulfone 3, however, plays only a minor role on the overall structure of the two compounds. A similar behaviour was found for a series of sulphur-containing heterocycles in which the oxidation of the sulphur atom has almost no impact on the geometrical parameters of the heterocycles.54,55 The only bond distances which are somewhat influenced by oxidation are S–CFe and S–CH2 (Table 1), whereby the corresponding bonds in 3, as compared to 1, are shortened by 0.02 Å, as previously observed by Petrov.54,55 In both compounds, the thiopyran ring adopts a half-chair conformation to limit the steric repulsion between the different substituents (Fig. 2). In these carbon-bridged diferrrocenyl complexes, the Fe⋯Fe distances are 5.6377(6) Å (1), 5.6824(9) Å (3A) and 5.6785(9) Å (3B), respectively. These values are comparable to those found in analogous carbon-bridged diferrrocenyl compounds.56 Interestingly, the dihedral angles between the two planes of the covalently bonded cyclopentadienyl rings are quite acute in 1 (61.4°) and molecule 3A (63.1°), while in 3B this dihedral angle is normal at 76.6°.56

UV-Vis spectroscopy, electrochemistry and spectroelectrochemistry

The electronic properties of the ferrocenyl-functionalised compounds 1–3 were studied by using UV-Vis, cyclic (= CV) and square wave voltammetry (= SWV) and in situ UV-Vis/NIR spectroelectrochemistry.

Compounds 1–3 show relatively weak absorptions in the visible region and stronger absorptions at higher energies (Fig. 3) as it is characteristic for ferrocene derivatives.57,58

TD-DFT (= Time Dependent Density-Functional Theory) calculations (Fig. 3) performed for 1 predict eight lowest-energy transitions between 450 and 530 nm in which mainly Fe-centred molecular orbitals of 3d-character are involved. The low energy spectral features are, thus, assigned to an unresolved series of broad overlapping bands resulting from ferrocene-centred d-d transitions.\(^\text{40,59,60}\)

The electrochemical measurements (CV and SWV) were performed under an argon atmosphere in dichloromethane solutions containing [Bu\(_4\)N][B(C\(_6\)F\(_5\))\(_4\)] (0.1 mol L\(^{-1}\)) as supporting electrolyte at a scan rate of 100 mV s\(^{-1}\) at 25 °C. The data of the cyclic voltammetry experiments are summarised in Table 2. All potentials are referenced to the FcH/FcH\(^{+}\) redox couple.\(^\text{61}\) The voltammograms of 1–3 are shown in Fig. 5.

As it can be seen from Fig. 5, both ferrocenyl groups in 1–3 can be oxidised separately showing two well-resolved reversible one-electron oxidation steps. The chemical oxidation of the sulphur atom in the neighbouring position to the ferrocenyl units leads to an anodic shift of the both Fe-based oxidation processes, \(E^\circ_1\) from 90 mV (1) over −15 mV (2) to 5 mV (3) and \(E^\circ_2\) from 275 mV (1) over 355 mV (2) to 375 (3), respectively. This chemical oxidation process increases the group-electronegativity at the sulfur (for example, see group electronegativity: \(-\text{SMe} = 2.592; \quad -\text{SOMe} = 2.841; \quad -\text{SO}_2\text{Me} = 2.998\)\(^\text{62}\) and hence, reduces the electron density at the ferrocenyl groups due to the increased electron withdrawing effect. This trend is also reproduced in the results of the DFT calculations (see below). The Fe-centred occupied frontier orbitals undergo substantial stabilisation upon oxidation of the sulphur atom. For example, the HOMO energy in 3 is about 60 mV smaller than that in non-oxidised 1 (Fig. 4).

The redox separation between the 1\(^{\text{st}}\) and the 2\(^{\text{nd}}\) oxidation processes, however, is not affected by the different degree of the sulphur oxidation and is ca. 370 mV throughout the series. Due to the use of [Bu\(_4\)N][B(C\(_6\)F\(_5\))\(_4\)]\(^\text{125,63-69}\) as weakly coordinating counter-ion within the electrolyte, the ion-pairing effects are minimised\(^\text{70-72}\) and thus, the electrostatic stabilisation forces between the ferrocenyl groups are increased, when compared with diferrocenylmethane measured in [Bu\(_4\)N][ClO\(_4\)]\(^\text{3.7}\) (\(\Delta E^\circ = 120 \, \text{mV}\)).

The UV-Vis/NIR spectroelectrochemical measurements were performed in an OTTLE (= Optically Transparent Thin-Layer Electrochemistry) cell\(^\text{74}\) using an analyte concentration of 2.0 mmol L\(^{-1}\) and [Bu\(_4\)N][B(C\(_6\)F\(_5\))\(_4\)] (0.1 mol L\(^{-1}\)) as supporting electrolyte in dichloromethane (1–3) or acetonitrile (2). The UV-Vis/NIR spectra are depicted in Fig. 6 (1), 7 (2), and 8 (3). The spectrum measured in acetonitrile (2) is shown in Fig. S5.\(^\dagger\)

The appropriate compounds were oxidised by stepwise increasing the potentials (step width 25, 50 and 100 mV). Thus, the studied compounds 1–3 underwent oxidation to the mono-cationic 1–3\(^+\) and di-cationic 1\(^{2+}\)–3\(^{2+}\) species, respectively. After complete oxidation, each sample was reduced at −200 mV to prove the reversibility of the redox processes. The resulting UV-Vis/NIR spectra were identical to those of the starting molecules. During the oxidation of 1–3 a broad band with a very low intensity (\(\epsilon_{\text{max}} = 100 \, \text{L mol}^{-1} \text{cm}^{-1}\)) between 1000 and 3000 nm appeared (Fig. 6–8). A further increase of the potential resulted in the decrease of this band. Such a behaviour is typically observed for intervalence charge transfer (= IVCT) absorptions.\(^\text{2,13}\) The experimental spectra can be deconvoluted into three Gaussian-shape bands assigned to an

\(^a\) Potentials vs. FcH/FcH\(^+\), scan rate 100 mV s\(^{-1}\) at glassy carbon electrode of a 1.0 mmol L\(^{-1}\) solution in dry dichloromethane; 0.1 mol L\(^{-1}\) [N\(^{+}\)Bu\(_4\)][B(C\(_6\)F\(_5\))\(_4\)] as supporting electrolyte at 25 °C. \(^\dagger\) \(E^\circ = \) Formal potential. \(^\dagger\) \(\Delta E^\circ = \) potential difference between the oxidation and the reduction potential. \(^\dagger\) \(\Delta E^\circ = \) potential difference between the two ferrocenyland related redox processes \(E^\circ_2-E^\circ_1\).
IVCT, a ligand field transition, and a band representing the edge to the higher energy absorptions. The sum of these three Gaussian-shaped bands fits almost exactly with the experimental spectra. The deconvolution reveals the intensity \( \varepsilon_{\max} \), the full width-at-half-height \( \Delta \nu_{1/2} \) and the \( \nu_{\max} \) values for the IVCT component. The solvent polarity change from \( P = 3.1 \) (dichloromethane) to \( P = 5.8 \) (acetonitrile), resulting in a shift of the \( \nu_{\max} \) value from 5250 cm\(^{-1}\) to 7525 cm\(^{-1}\). It is remarked that strong solvatochromic shifts are expected for IVCT absorption bands being of distinct charge transfer character. Thus, the IVCT assignment of the observed NIR absorption features (Fig. 6–8 and Table 3) is further substantiated. The appearance of low energy ligand field transitions is characteristic for ferrocenyl containing compounds as for example demonstrated by UV/Vis-NIR measurements of mono ferrocenyl thiophenes. The numerical data derived from the deconvolution procedure is summarised in Table 3. However, the data should be

Conclusions

Within this study it was shown that 2,2-diferrocenyl-4,5-dimethyl-3,6-dihydro-2H-thiopyran (1) is readily available through a hetero-Diels–Alder cyclo-addition reaction of difero-
cenythioketone with 2,3-dimethyl-1,3-butadiene. Stepwise oxida-
tion of the sulphur atom in 1 afforded the corresponding S-oxides: 2,2-diferrocenyl-4,5-dimethyl-3,6-dihydro-2H-thiopyran-1-oxide (2, sulfoxide) and 2,2-diferrocenyl-4,5-dimethyl-
3,6-dihydro-2H-thiopyran-1,1-dioxide (3, sulfone). Electro-
chemical measurements on 1–3 revealed well separated redox
events related to the two ferrocenyl groups. The corresponding $E'$ and $E''$ potentials are shifted anodically in the order of $1 < 2 < 3$. This is accounted for the increasing electron-withdrawing
effect of the adjacent S, SO, and SO$_2$ fragments on the ferro-
cenyl groups. Thus, the Fe-centred orbitals in 2 and 3 are more stabilised than in 1. A single crystal X-ray diffraction study of 1 and 3 revealed that the chemical oxidation of the sulphur atom has only a negligible influence on the overall molecule’s
geometry (bond lengths and angles). Nevertheless, the X-ray
analyses have also shown that the Fe–Fe distances in 1 and 3 are shorter than that in Fe$_2$CH$_2$ (5.765 Å). This effect is
ascribed to the steric hindrance exerted by the 4,5-dimethyl-
3,6-dihydro-2H-thiopyran ring. It has been also demonstrated
that the cyclic 4,5-dimethyl-3,6-dihydro-2H-thiopyran group
enables weak metal–metal electronic interactions in the mono-
oxidised species 1–3, as confirmed by the appearance of
weak IVCT absorptions characteristic for mixed-valent systems
(= MV). This allows to categorise cations 1–3 as weakly
coupled class II MV systems according to Robin and Day. Moreover, the extent of metal–metal electronic interactions in
1–3 does not change significantly with the oxidation state of
the sulphur atom (sulphide (1) → sulfoxide (2) → sulfone (3)). In
summary, our results demonstrate that sterically demand-
ing 2H-thiopyran-derived bridges enable metal–metal elec-
tronic interactions between redox centres in mixed-valent
molecular systems. In the studied MV species, most probably,
the “through space” mechanism is dominantly operative.

Experimental section

General data and reagents

All reactions were carried out under an atmosphere of argon
using standard Schlenk techniques. Chromatographic
separations were carried out using silica gel 60 (Merck,
230–400 mesh ASTM). Dichloromethane was purified by distil-
lution from CaH$_2$ prior to use and methanol was purified by
distillation over magnesium. 2,3-Dimethyl-1,3-buta diene,
m-chloroperoxybenzoic acid, 30% hydrogen peroxide and
selenium dioxide were purchased from commercial suppliers
and were used without further purification.

Instruments

$^1$H NMR (600 MHz) and $^{13}$C(3H) NMR (150 MHz) spectra were
recorded with a Bruker Avance III 600 spectrometer operating
at 298 K in the Fourier transform mode. Chemical shifts are
reported in δ units (ppm) using as residual CDCl$_3$ ($^1$H δ 7.26 ppm,
$^{13}$C δ 77.00 ppm) as the reference. Infrared spectra
were recorded with a FTIR Nexus Nicolet apparatus. Mass
spectra were recorded with a Varian 500-MS IT mass spectrom-
ter (ESI) or with a Finnigan Mat95 mass spectrometer (EI).
Microanalyses were determined by Analytical Services of the
Polish Academy of the Sciences, Łódź. UV-Vis absorption
spectra were recorded with a Varian Cary 300 double beam
spectrometer.

DFT computations and spectroelectrochemical measurements

The geometry optimisations and electronic transition calcula-
tions were performed using density-functional theory
(= DFT) and time dependent density-functional theory (= TD
DFT) with Becke’s three parameter functional$^{78}$ with the
non-local Lee–Yang–Parr correlation functional (B3LYP)$^{79}$ and
the standard 6-31G(d,p) basis set as implemented in the Gaussian
09 program package.$^{80}$

Electrochemical measurements of 1.0 mmol L$^{-1}$ dichloro-
methane solutions of 1–3 were performed in a dried, argon
purged cell at 25 °C with a Radiometer Voltalab PGZ 100
electrochemical workstation interfaced with a personal computer.
Dichloromethane solutions (0.1 mol L$^{-1}$) containing [Bu$_4$N]$_2$
[B(C$_6$F$_5$)$_4$]$_2$ were used as supporting electrolyte. For the
measurements a three electrode cell containing a Pt auxiliary
electrode, a glassy carbon working electrode (surface area
0.031 cm$^2$) and an Ag/Ag$^+$ (0.01 mmol L$^{-1}$ [AgNO$_3$]) reference
electrode fixed on a Luggin capillary was applied. The working
electrode was pretreated by polishing on a Buehler microcloth
first with a 1 micron and then with a 1/4 micron diamond
paste. The reference electrode was constructed from a silver
wire inserted into a 0.01 mmol L$^{-1}$ [AgNO$_3$] and 0.1 mol L$^{-1}$
[Bu$_4$N][B(C$_6$F$_5$)$_4$] acetonitrile solution in a Luggin capillary with
a Vycor tip. This Luggin capillary was inserted into a second
Luggin capillary containing a 0.1 mol L$^{-1}$ [Bu$_4$N][B(C$_6$F$_5$)$_4$]
dichloromethane solution and a Vycor tip. Experiments under the same conditions showed that all reduction and oxidation potentials were reproducible within 5 mV.

Experimental potentials were referenced against an Ag/Ag+ reference electrode but the presented results are referenced against ferrocene as an internal standard as required by IUPAC.61 To achieve this, each experiment was repeated in the presence of 1 mmol L−1 decamethylferrocene (= Fe∗). Data were processed on a Microsoft Excel worksheet to set the formal reduction potentials of the FeH/FeH+ couple to 0.0 V.

Under our conditions the Fe∗/FeH+ couple was at −619 mV vs. FcH/FeH+ (ΔE‡ = 60 mV), while the FeH/FeH+ couple itself was at 220 mV vs. Ag/Ag+ (ΔE‡ = 61 mV). Spectroelectrochemical UV-Vis/NIR measurements of 2.0 mmol L−1 solutions of 1–3 in dichloromethane (1–3) or acetonitrile (2) containing 0.1 mol L−1 of [Bu4N][B(C6F5)4] as the supporting electrolyte were performed in an OTTLE (Optically Transparent Thin-Layer Electrochemistry) cell with a Varian Cary 5000 spectrophotometer at 25 °C. The values obtained by deconvolution could be reproduced within εmax, 100 L mol−1 cm−1; εmax, 50 cm−1 and Δν1/2, 50 cm−1.

**Synthesis of 2,2-diferrocenyl-4,5-dimethyl-3,6-dihydro-2H-thiopyran (1)**

A mixture of diferrocenyl thiketone (399 mg, 0.96 mmol) and thiopyran (1) was stirred in a tightly closed glass-tube for 50 h at 75 °C. Afterwards, the reaction mixture was evaporated to dryness and the thus obtained solid was subjected to column chromatography on SiO2 (chloroform–hexane, ratio 1/1 (v/v)). Crystallization from chloroform–hexane gave pure 1 as red crystals in a 65% yield (309 mg).

1H NMR (600 MHz, CDCl3): δ = 4.62 (bs, 2H, C3H4), 4.20 (bs, 2H, C3H4), 4.13 (bs, 2H, C3H4), 4.11 (bs, 2H, C3H4), 4.07 (s, 10H, C3H4), 3.00 (s, 2H, CH2), 2.64 (s, 2H, CH2), 1.85 (s, 3H, CH3), 1.74 (s, 3H, CH3). 13C NMR (150 MHz, CDCl3): δ = 126.6, 124.3, 97.1, 69.0, 66.9, 66.8, 66.7, 66.4, 44.5, 43.3, 31.3, 20.4, 19.4. FTIR (KBr): 3088, 2989, 2911, 2872, 1628, 1443, 1409, 1301, 1264, 1106, 1032, 1000, 824, 485 cm−1. MS (ESI): m/z = 496 (MNa+), 513 (MH+). MS (EI, 70 eV): m/z = 512 (M+). HRMS: m/z = 512.058 (Calc. for C27H25OSFe2). Anal. Calcd for: C27H25OSFe2: C, 61.39; H, 5.81; S, 6.71%.

**Synthesis of 2,2-diferrocenyl-4,5-dimethyl-3,6-dihydro-2H-thiopyran-1,1-dioxide (3)**

m-Chloroperoxybenzoic acid (= MCPBA) (45 mg, 0.26 mmol) was added to a stirred solution of sulphone 2 (100 mg) in dichloromethane (20 mL) at −20 °C. The resulting reaction mixture was stirred at −20 °C for 2 h and then for an additional 24 h at ambient temperature. Afterwards, the 2nd portion of MCPBA (45 mg, 0.26 mmol) was added and the mixture was stirred at ambient temperature for another 24 h. Subsequently, a saturated NaHCO3 solution was added in single portion and the resulting mixture was extracted with dichloromethane. The organic layer was washed with brine, separated and dried over anhydrous MgSO4. Then all volatile materials were evaporated. The residue was subjected to preparative TLC on SiO2 (diethyl ether–hexane, ratio 1/1 (v/v) as eluent). Sulfone 3 was obtained as a red solid in 21% (21 mg) yield.

1H NMR (600 MHz, CDCl3): δ = 4.47 (bs, 2H, C3H4), 4.24 (s, 4H, C3H4), 4.21–4.20 (pq, JH,H = 1.98 Hz, 1.74 Hz, 2H, C3H4), 4.13 (s, 10H, C3H4), 3.32 (s, 2H, CH2), 3.06 (s, 2H, CH2), 1.91 (s, 3H, CH3), 1.69 (s, 3H, CH3). 13C NMR (150 MHz, CDCl3): δ = 127.0, 119.9, 89.0, 69.6, 68.7, 67.6, 67.5, 67.2, 62.5, 51.6, 44.5, 19.9, 19.6. FTIR (KBr): 3031, 2918, 2857, 1629, 1406, 1104, 1053 (s, S=O), 1031, 1000, 824, 485 cm−1. MS (ESI): m/z = 528 (MNa+), 565 (M+). MS (EI, 70 eV): m/z = 546 (M+). HRMS: m/z = 528.051 (Calc. for C27H24O2SFe2). Anal. Calcd for: C27H24O2SFe2: C, 61.39; H, 5.34; S, 6.07%. Found: C, 61.20; H, 5.48; S, 5.91%.

**Single-crystal X-ray structure analysis of 1 and 3**

Red crystals of 1 were obtained by slow evaporation of a chloroform–hexane solution containing 1, while red crystals of 3 were grown by the slow evaporation of a diethyl ether–hexane solution containing 3 at ambient temperature. Data were collected with a Stoe Image Plate Diffraction system equipped with a φ circle goniometer using Mo Kα graphite monochromatic radiation (λ = 0.71073 Å) with φ range 0–20°. The structures were solved by direct methods applying the program SHELXS-97, while the refinement and all further calculations were carried out with SHELXL-97.82,83 The hydrogen atoms
were included in calculated positions and treated as riding atoms using the SHELXL default parameters, except for the N–H hydrogen atoms which were located on the Fourier difference map and refined. The non-hydrogen atoms were refined anisotropically using weighted full-matrix least-square on \( F^2 \). Crystallographic details for 1 and 3 are summarized in Table S1 (see ESI†).

CCDC 1031233 (1) and 1031234 (3) contain the supplementary crystallographic data for this paper.
